The NASA STI Program ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program plays a key part in helping NASA maintain this important role.

The NASA STI Program provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Program's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

Scientific and Technical Aerospace Reports

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the International Aerospace Database, managed by the NASA Scientific and Technical Information (STI) Program.

Inside this issue you will find:

Front Matter
A typical citation and abstract sample explaining the standard format, which includes codes for ordering reports.

An Abstract Section
Citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.

An Index Section
- Subject
- Personal author
- Corporate source
- Contract number
- Report number.

Appendix
A guide for ordering cited reports, registering with the NASA STI Program, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors companion journals, *International Aerospace Abstracts (IAA)*, and *NASA Open Volumes on Aerospace (NOVA)*. They list abstracts of the open literature on aerospace subjects available worldwide. IAA is available from the American Institute of Aeronautics and Astronautics (AIAA), and *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Reports found in *STAR* are also available through the NASA online retrieval service, RECON, and the Aerospace Database through DIALOG.

The NASA STI Program gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Program, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) **499**

02 AERODYNAMICS **499**
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also 34 *Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY **510**
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION **512**
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE **514**
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION **516**
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER **517**
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL **520**
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) **527**
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) **529**
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS **532**
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) **532**
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES **533**
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION **533**
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING **537**
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE **539**
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance*, *39 Structural Mechanics*, and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION **544**
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER **548**
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power*, *28 Propellants and Fuels*, *44 Energy Production and Conversion*, and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) **554**

24 COMPOSITE MATERIALS **554**
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY **561**
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS **567**
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS **575**
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS **583**
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power*, *20 Spacecraft Propulsion and Power*, and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING **586**
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) **595**
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR **597**
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING **618**
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER **627**
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY **648**
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS **653**
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING **660**
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY **665**
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS **669**
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) **683**

43 EARTH RESOURCES AND REMOTE SENSING **684**
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION **700**
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION **705**
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS **711**
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY **718**
Includes weather forecasting and modification.

48 OCEANOGRAPHY **725**
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) **727**

52 AEROSPACE MEDICINE **731**
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES **734**
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT **736**
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY **739**
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) **739**

60 COMPUTER OPERATIONS AND HARDWARE **740**
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE **742**
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS **758**
Includes computer networks and special application computer systems.

63 CYBERNETICS **761**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **767**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **772**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **774**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS **775**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) **775**
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS **776**
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS **778**
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS **788**
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS **790**
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS **794**
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS **803**
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS **816**
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) **818**
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT **819**
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE **820**
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS ..... **N.A.**
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY **827**
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION **828**
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) 828

89 ASTRONOMY 828
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS 834
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION 841
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS 844
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION 846
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The application of advanced control concepts to air breathing engines may yield significant improvements in aircraft/engine performance and operability. Screening studies of advanced control concepts for air breathing engines were conducted by three major domestic aircraft engine manufacturers to determine the potential impact of concepts on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed advanced control concepts was formulated and evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation specific aircraft/engine combinations were considered: a Military High Performance Fighter mission, a High Speed Civil Transport mission, and a Civil Tiltrotor mission. Each of the advanced control concepts considered in the study are defined and described. The concept potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts are determined. Finally, the concepts are ranked with respect to the target aircraft/engine missions. A final report describing the screening studies was prepared by each engine manufacturer. Volume 1 of these reports describes the studies performed by Pratt & Whitney. Author (revised)

AVERAGING TECHNIQUES FOR STEADY AND UNSTEADY CALCULATIONS OF A TRANSONIC FAN STAGE

M. L. Wyss (Cincinnati Univ., OH.), R. V. Chima, and D. L. Tweedt Jul. 1993 12 p Presented at the 24th AIAA Fluid Dynamics Conference, Orlando, FL, 6-9 Jul. 1993; sponsored by AIAA

(NASA-TM-106231; E-7950; NAS 1.15:106231; AIAA Paper 93-3065)

Copyright Avail: CASI HC A03/MF A01

It is often desirable to characterize a turbomachinery flow field with a few lumped parameters such as total pressure ratio or stage efficiency. Various averaging schemes may be used to compute these parameters. The momentum, energy, and area averaging schemes are described and compared. The schemes were compared for two computed solutions of the midspan section of a transonic fan stage: a steady averaging-plane solution in which average rotor outflow conditions were used as stator inflow conditions, and an unsteady rotor-stator interaction solution. The solutions were computed on identical grids using similar Navier-Stokes codes and an algebraic turbulence model. The unsteady solution is described, some unsteady flow phenomena are discussed, and the steady pressure distributions are compared. Despite large unsteady pressure fluctuations on the stator surface, the steady pressure distribution matched the average unsteady distribution almost exactly. Stator wake profiles, stator loss coefficient, and stage efficiency were computed for the two solutions with the three averaging schemes and are compared. In general, the energy averaging scheme gave good agreement between the averaging-plane solution and the time-averaged unsteady solution, even though certain phenomena due to unsteady wake migration were neglected.

[ACTIVITIES OF BOMBARDIER, INC.] Annual Report, period ending 31 Jan. 1993

1993 57 p Original contains color illustrations

(ISBN-2-921393-11-5; CTN-93-60863) Copyright Avail: CASI HC A04/MF A01

Bombardier Inc. is a designer, manufacturer, and distributor of transportation equipment and other products and services related to its technology. Its corporate office is in Montreal, Quebec, and its production facilities are located in Canada, the United States, Mexico, Austria, Belgium, France, Finland, and the United Kingdom. Bombardier's Transportation Equipment Group manufactures railroad cars, locomotives, and related products and services. Its aerospace group includes Canadair, maker of the Canadair Regional Jet and the CL-415 amphibious aircraft; de Havilland Inc. (Canada), maker of the Dash-8 turboprop; Learjet Inc. (Wichita, Kansas), maker of the Learjet series of business aircraft; and Short Brothers (Northern Ireland), maker of military aircraft, components, and defense systems. Bombardier also has a consumer products group that makes snowmobiles, water craft and other items. In this 1992-93 annual report, highlights of activities and financial statements and summaries are presented. For 1992-93, Bombardier's income before taxes was $150.9 million on consolidated revenues of $4,448 million. Total aerospace sales were $2.2 billion, with a sales backlog of $3.3 billion.

THE DEVELOPMENT OF INSPECTION AND REPAIR METHODS FOR THE C-17 AFT CARGO DOOR Final Report

Robert Fredell Nov. 1992 54 p

(LR-704; ETN-93-94421) Avail: CASI HC A04/MF A01

The development of field level inspection and repair methods for the C-17 aft cargo door skins, constructed from ARALL 3, are reported. ARALL 3 is an advanced aramid/aluminum laminated sheet material with high strength and excellent fatigue resistance. The major areas of interest covered are: the effect of impact on the structural strength and durability; the effects of scratches on strength and durability; the limits of laminate workshop properties as they apply to repair; the most effective means of on-aircraft nondestructive inspection; and the development of acceptable practices for repair of damaged ARALL structures. The test program was focused on the following objectives: determining if the second cure cycle used in the manufacture of the door affects the fatigue and damage tolerance characteristics of the material; determining the effect of various levels of incidental damage on fatigue and residual strength properties of ARALL 3, and specifying what damage requires repair; and evaluating the structural effectiveness and ease of application of various concepts for base level repair of ARALL 3. The obtained results, conclusions, and recommendations are given.

ESA

02 AERODYNAMICS

Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery.

A COMPARISON OF TWO FORMULATIONS FOR HIGH-ORDER ACCURATE ESSENTIALLY NON-OSCILLATORY SCHEMES Final Report

Jay Casper (Vigyan Research Associates, Inc., Hampton, VA.), Chi-Wang Shu (Brown Univ., Providence, RI.), and H. L. Atkins (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.) Washington Jun. 1993 27 p Submitted for publication

(Contracts NAS1-19480; NAS1-19672; NAG1-1145; RTOP 505-90-52-01)

(NASA-CR-191476; NAS 1.26:191476; ICASE-93-27) Avail: CASI HC A03/MF A01

The finite-volume and finite-difference implementations of high-order accurate essentially non-oscillatory shock-capturing schemes are discussed and compared. Results obtained with fourth-order accurate algorithms based on both formulations are examined for accuracy, sensitivity to grid irregularities, resolution of waves that are oblique to the mesh, and computational efficiency. Some algorithm modifications that may be required for a given application are suggested. Conclusions that pertain to the relative merits of both formulations are drawn, and some circumstances for which each might be useful are noted.

NUMERICAL SIMULATION OF HYPERSONIC FLOW FOR THE DESIGN OF THE H-2 ORBITING PLANE (HOPE), PART 3 [HOPE NO GOKUCHOUONSOKURYUU SUUCHI SHIMYURESHON]

Yukimitsu Yamamoto Jul. 1992 97 p In JAPANESE Prepared in cooperation with NSDA, Tokyo, Japan
(NAL-TR-1168-Pt-3; JTN-93-80500-Pt-3) Avail: CASI HC A05/MF A02

Three-dimensional upwind flux-split Navier-Stokes codes are applied to examine hypersonic flow around HOPE-01 (H-2 Orbiting Plane) configurations. Numerical results are compared with experimental data from the National Aerospace Lab (NAL) hypersonic wind and shock tunnel. In order to enlarge the applicability of Computational Fluid Dynamics (CFD) for a more practical design purpose, the effects of rudder and elevon deflections were numerically investigated. In addition, to study the aerodynamic and aerothermodynamic environments at the high Mach numbers expected in the HOPE flight trajectory, computations were conducted using a Mach number of 12.0 and 15.0. Aerothermodynamic heating distributions were compared in detail with Calspan's shock tunnel data and fairly good quantitative agreements were obtained. Real gas effects were also analyzed using a chemical non-equilibrium Navier-Stokes code which was developed by combining finite-rate chemical reactions to the currently used perfect gas flux-split code. A fully implicit Alternative Directional Implicit (ADI) scheme is employed to avoid the stiffness problem occurring in the time integration process. Typical real gas effects on aerodynamic characteristics are revealed. This work was conducted as joint research of NAL and the National Space Development Agency (NASDA). Author (NASDA)

N94-12951# National Aerospace Lab., Tokyo (Japan). Dynamic Wind Tunnel Test Group.
IDENTIFYING THE NAL SPACEPLANE AERODYNAMIC MODEL USING DYNAMIC WIND TUNNEL TESTS [KEBURU SHIJI DOUTEKI FUUDOU SHIKEN NIYORU NAL SUPESUPUREN NO KUURIKI MODERU DOUTEI]
Masaaki Yanagihara Jul. 1992 45 p In JAPANESE
(NAL-TR-1171; JTN-93-80501) Avail: CASI HC A03/MF A01

An aerodynamic model identification technique utilized by the National Aerospace Laboratory (NAL) was applied to dynamic wind tunnel tests using a cable mounted model to extract aerodynamic parameters of the NAL Spaceplane. The estimated static parameters were evaluated by comparisons with static wind tunnel test results, whereas those for the dynamic parameters were evaluated by comparison with theoretically estimated values. In addition, mathematical flight simulations using both static and dynamic parameters were conducted for the total evaluation. The simulated results were subsequently compared with the wind tunnel test data, and satisfactory correlation was achieved, thereby, demonstrating the effectiveness of the dynamic tests. IMPROVED AEROPREDICTION CODE. PART 1: SUMMARY OF NEW METHODS AND COMPARISON WITH EXPERIMENT
Frank G. Moore, Thomas C. Hymer, and Roy M. Mcinville May 1993 156 p
(AD-A266015; NSWCDD/TR-93/91) Avail: CASI HC A08/MF A02

A new and improved version of the Naval Surface Warfare Center, Dahlgren Division aeroprediction code (AP93) was developed. The new code contains new technology that allows planar aerodynamics of axisymmetric solid rocket-type weapons to be computed with engineering accurately over the entire Mach number range and for angles of attack to 30 deg. New technology developed and included in the AP93 includes: a new engineering method to compute aeroheating information at a high Mach number; extension of the second-order shock-expansion theory to include real-gas effects, including several new pressure prediction techniques; an improved body-alone nonlinear normal-force method; new methods for computing nonlinear aerodynamics of wing alone, wing body, and body wing due to angle of attack, and wing body due to control deflection; and a new base-drng database and improved empirical base-drag estimation technique. A WALL INTERFERENCE ASSESSMENT/CORRECTION SYSTEM Semiannual Report No. 4, Jan. - Jun. 1993
Ching F. Lo 1993 45 p
(Grant NAG2-733)
(NASA-CR-194174; NAS 1.26:194174) Avail: CASI HC A03/MF A01

A Wall Signature method originally developed by Hackett was selected to be adapted for the Ames 12-ft Wind Tunnel Wall Interference Assessment/Correction (WIAC) System in the project. This method uses limited measurements of the static pressure at the wall, in conjunction with the solid wall boundary condition, to determine the strength and distribution of singularities representing the test article. The singularities are used in turn for estimating wall interference at the model location. The lifting interference will be treated separately by representing in a horseshoe vortex system for the model's lifting effects. The development and implementation of a working prototype will be completed, delivered, and documented with a software manual. The WIAC code will be validated by conducting numerically simulated experiments rather than actual wind tunnel experiments. The simulations will be used to generate both free-air and confined wind-tunnel flow fields for each of the test articles over a range of test configurations. Specifically, the pressure signature at the test section wall will be computed for the tunnel case to provide the simulated 'measured' data. These data will serve as the input for the WIAC method - Wall Signature method. The performance of the WIAC method then may be evaluated by comparing the corrected parameters with those for the free-air simulation. The following two additional tasks are included in the supplement No. 1 to the basic Grant. On-line wall interference calculation: The developed wall signature method (modified Hackett's method) for Ames 12-ft Tunnel will be the pre-computed coefficients which facilitate the on-line calculation of wall interference; and support system effects estimation: The effects on the wall pressure measurements due to the presence of the model support systems will be evaluated. Author (revised)

AERODYNAMICS OF A SPHERE AND AN OBLATE SPHEROID FOR MACH NUMBERS FROM 0.6 TO 10.5 INCLUDING SOME EFFECTS OF TEST CONDITIONS
M. Leroy Spearman and Dorothy O. Braswell Aug. 1993 26 p
(RTOP 505-69-20-01)
(NASA-TM-109016; NAS 1.15:109016) Avail: CASI HC A03/MF A01

Wind-tunnel tests were made for spheres of various sizes over a range of Mach numbers and Reynolds numbers. The results indicated some conditions where the drag was affected by changes in the afterbody pressure due to a shock reflection from the tunnel wall. This effect disappeared when the Mach number was increased for a given sphere size or when the sphere size was decreased for a given Mach number. Drag measurements and Schlieren photographs are presented that show the possibility of obtaining inaccurate data when tests are made with a sphere too large for the test section size and Mach number. Tests were also made of an oblate spheroid. The results indicated a region at high Mach numbers where inherent positive static stability might occur with the oblate-face forward. The drag results are compared with those for a sphere as well as those for various other shapes. The drag results for the oblate spheroid and the sphere are also compared with some calculated results. Author

NUMERICAL STUDY OF THE EFFECTS OF ICING ON VISCOUS FLOW OVER WINGS Semiannual Progress Report, 1 Jan. - 30 Jun. 1993
L. N. Sankar Jul. 1993 38 p
(Grant NAG3-768)
(NASA-CR-193306; NAS 1.26:193306) Avail: CASI HC A03/MF A01

The progress made during the period 1 Jan. - 30 Jun. 1993 on the numerical study of the effects of icing on viscous flow over wings is summarized. The tasks performed were development of 3-D boundary layer methods for accurate estimates of the velocity field and surface heat transfer rates in the vicinity of the leading edge ice shape; studies of the effects of icing on 3-D highlift system performance; and continued improvement and validation of the 3-D Navier-Stokes solver. Results are discussed. CASI

A TIME-ACCURATE NUMERICAL METHOD FOR CHEMICALLY REACTING FLOWS AT ALL MACH NUMBERS Ph.D. Thesis
James P. Withington 1992 223 p
Avail: Univ. Microfilms Order No. DA9311744

A time-accurate implicit scheme for solving chemically reacting flows

over a wide range of Mach numbers is developed and applied to selected problems of quasi one-dimensional and two-dimensional reacting flow. The motivation was to develop a unified solution algorithm capable of generating compressible flow solutions to flows that exhibit incompressible behavior in all or parts of the domain. The new formulation is based on the complete set of conservation laws, with a full account of finite-rate chemistry and thermodynamic and transport property variations with temperature and species concentration. To circumvent the computational difficulties at low Mach numbers common to typical schemes based on conservation law variables, the governing equations were modified by scaling the pressure term in the momentum equation and rederiving the conservative form of the governing equations from their non-conservative forms using a new equation of continuity based on a scaled pressure, rather than density. The result is that a well conditioned pseudo-time derivative vector replaces the original time derivative vector of conservation law quantities. Time-marching then evolves in a system of new dependent variables that include pressure rather than density. The advantage to this treatment is that numerically, pressure is much more sensitive to the flow solution than is the density. This is particularly true for low speed flows where density and temperature are nearly constant. The governing equations in the pseudo-time domain do not exhibit the stiffness and truncation error common in the standard density-based system. The equations are then solved using a dual time-stepping integration technique. While standard implicit schemes are implemented in pseudo-time, the converged solution represents a physically time-accurate solution at a particular physical time level. The technique is shown to be very robust, exhibiting convergence independent of Mach number for flows ranging from molecular diffusion velocity to supersonic speed. The equations cast in the new pseudo-time form behave similarly to density-based schemes in the moderate to high Mach number range, yet also offer the performance of low speed solvers for incompressible flows. Furthermore, it is able to achieve high-order temporal accuracy with only a fractional increase in computational cost due to the dual time-stepping procedure. The scheme is validated and capabilities of the algorithm are illustrated in its application to selected steady-state and transient flow problems including acoustic wave propagation, flame dynamics, and combustor flow fields of high contraction ratio. Finally, the scheme is applied to the study of combustion instabilities in a rocket combustion chamber. Dissert. Abstr.

For over twenty years designers at Sandia National Laboratories have developed various parachute simulation codes to model deployment, inflation, loading, trajectories, aircraft downwash, and line sail. In addition to these codes, material property data bases have been acquired. Recently we have initiated project to integrate these codes and data bases into a single software tool entitled SPARSYS (Sandia PARachute SYstem Simulation). We have constructed a graphical user interface as the driver and framework for SPARSYS. In this paper we present a status report on SPARSYS describing progress in developing and incorporating independent modules, in developing an integrated trajectory package, and in developing a materials data base including high-rate-of-strain data. THREE-DIMENSIONAL STRUCTURE OF STRAIGHT AND CURVED PLANE WAKES

James H. Weygandt and Rabindra D. Mehta Sep. 1993 339 p

(Contract NCC2-55)

(NASA-CR-194420; NAS 1.26:194420; JIAA-TR-110) Avail: CASI HC A15/MF A03

Although the plane wake is marked by the formation of strong spanwise vortices, the initially two-dimensional Karman-like vortices soon develop a three-dimensional structure in the form of secondary streamwise vortices. So far, this streamwise vortex structure has been studied mostly through flow visualization and at relatively low Reynolds numbers. The primary objective of the present program was to investigate the origin and evolution of the three-dimensional structure of straight and curved plane wakes at relatively high Reynolds numbers (Re(sub b) = 28,000) through detailed measurements of the mean and turbulent properties at several streamwise locations. The experiments were conducted in three phases. In the first phase, the development of a straight plane wake was investigated. In the second phase, the effects of imposed streamwise curvature on the wake development were examined. The streamwise curvature was of constant radius and very mild in terms of the curvature ratio (b/(square root of R) is less than 2 percent). In both the first and second phases, the role of initial conditions was examined in wakes generated from both untripped (laminar) and tripped (turbulent) initial boundary layers. In the third phase, the effects of injecting streamwise vorticity and the effects of increased Reynolds number on the tripped wake structure and development were investigated. Author (revised)

EXPLORATORY STUDY OF IN-PLANE STREAMLINE CURVATURE EFFECTS ON A TURBULENT BOUNDARY LAYER AT A MACH NUMBER OF 3 Final Technical Report, 27 Jan. 1989 - 26 Jan. 1990

Seymour M. Bogdonoff May 1991 4 p

(Grant NAG1-961)

(NASA-CR-193673; NAS 1.26:193673) Avail: CASI HC A01/MF A01

This report on a program to study in-plane streamline curvature effects in a turbulent boundary layer at a Mach number of 3. The original proposal, for a 3-year program to explore in-plane streamline curvature effects on a supersonic turbulent boundary layer using three-dimensional pressure fields generated by fins and wall geometry, ended after one year. The purpose of these tests was to compare these streamline curvature effects to the more classical two-dimensional curvature generated by wall shape and imposed pressure gradients, previously considered primarily in a plane normal to the floor. The studies were carried out in the Mach number of 3, 8 x 8 inch High Reynolds Number Supersonic Tunnel. The usual surface visualization and mean wall static pressures were supplemented by the use of many small high frequency wall static pressure gauges (Kulites) to get some indication of the amplification of boundary layer disturbances by the in-plane streamline curvature caused by the three-dimensional pressure fields imposed on the boundary layer. LOW-SPEED WIND TUNNEL TESTS ON FOUR TYPES OF JOINED-WING AIRCRAFT MODELS [HISHIGATA KETSUGOUYOKUKI 4 KEITAI NO TEISOKU FUUDOU JIKKEN]

Akihito Iwasaki, Toshimi Fujita, Hirotoshi Fujieda, and Naoto Takizawa Jul. 1992 24 p In JAPANESE

(NAL-TR-1167; JTN-93-80487) Avail: CASI HC A03/MF A01

Low-speed wind tunnel tests were conducted on four types of joined-wing aircraft models. Various ratios of horizontal tail to wing span were employed (40 percent, 60 percent, and 100 percent), and the leading-edge at the tip of horizontal tail was joined to the trailing-edge of the wing for three configurations. In addition, in one configuration, the tips of the horizontal tail and the wing were overlapped using the 100 percent ratio. The horizontal tail has minus 22 deg dihedral and minus 25 deg sweep angles (25 percent chord line). The main wing has respectively corresponding angles of 10 deg and 40 deg. The results indicated that the area and location of horizontal tail significantly effect the aerodynamic characteristics of the joined-wing aircraft. Author (NASDA)

LOW-SPEED WIND TUNNEL TESTS ON A JOINED-WING AIRCRAFT MODEL WITH VARIOUS UPPER-FIN [HISHIGATA KETSUGOUYOKUKI (UEYOKU TSUKI) NO TEISOKU FUUDOU JIKKEN]

Akihito Iwasaki, Toshimi Fujita, Hirotoshi Fujieda, and Naoto Takizawa Jul. 1992 27 p In JAPANESE

(NAL-TR-1169; JTN-93-80488) Avail: CASI HC A03/MF A01

Low-speed wind tunnel tests were conducted on a joined-wing aircraft model with various upper-fins (small wing-like surface fitted on the wing or the horizontal tail). The upper-fin was used to enhance direct side-force

control capability. In this case, the upper-fin was equipped with a plain flap as a rudder. The effects of the upper-fin on the aerodynamic characteristics of a joined-wing aircraft are described. A 0.6 ratio of the rear to front wing span was selected as the best condition. Four different shaped upper-fins were installed at the three locations on each wing at 0.6 half span. Reynolds number based on the mean aerodynamic chord was from 6.5 to 6.7 x 10(exp 5). The angle of attack was varied from zero to 25 deg., and the side-slip angle from zero to 15 deg. The results indicated that the upper-fin acts like a 'boundary layer fence' and protects wing tip stall when the upper-fin is installed on the wing. On the other hand, the upper-fin produced local flow separation over the wing, and this flow separation caused asymmetric lateral and directional characteristics with side-slip angle. Author (NASDA)

DEVELOPMENT OF A HIGH-SPEED MECHANICAL DRIVE SYSTEM FOR OSCILLATING AN ANNULAR BLADE ROW IN THE BENDING MODE [KOUSOKU KIKAISHIKI YOKUNETSU MAGE SHINDOU KASHIN SOUCHI TO SONO TOKUSEI]

Hideshi Oinuma and Hiroshi Kobayashi Jul. 1992 22 p In JAPANESE
(NAL-TR-1170; JTN-93-80489) Avail: CASI HC A03/MF A01

A novel high-speed mechanical drive system was developed which enables controlled-oscillations to be produced in an annular blade row in the bending mode, thus, allowing solutions to be obtained for cascade flutter in turbomachinery. This system makes possible to take unsteady aerodynamic force measurements in the National Aerospace Laboratory (NAL) Annular Cascade Test Facility at the realistic, reduced frequency level of supersonic flutter in turbomachinery. Blade row oscillation tests demonstrated that the presented system can controllably-oscillate, at up to 200 Hz, all 16 blades composing the annular blade row at a constant amplitude and interblade phase angles. Both aerodynamically unstable and stable conditions of the annular blade row can be controllably-oscillated while operating in a supersonic flow field. Author (NASDA)

(NAL-TR-1179; JTN-93-80492) Avail: CASI HC A03/MF A01

A locally-stationary time series analysis of nonstationary random responses in delta wings under supersonic conditions is presented. Since the partially supported cantilever delta wings failed during supersonic blowdown wind tunnel tests employing the injection and rejection systems, a safety device was introduced to prevent such failures. This enabled wing response data to be obtained from a test blow in which the dynamic pressure was increased at a constant speed with the Mach number being fixed. Estimated results indicated that the wing's critical values could be determined by applying the locally-stationary autoregressive process.

AN EXPERIMENTAL INVESTIGATION OF THE REDISTRIBUTION OF GAS STREAM TOTAL TEMPERATURE IN A HIGH TURNING ANGLE TRANSONIC PLANAR CASCADE Ph.D. Thesis

William Edward Carscallen Apr. 1990 170 p
(ISBN-0-315-60791-2; CTN-93-60734) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

Early testing at the National Research Council of Canada's (NRC) Highly Loaded Turbine Test Rig revealed an apparent redistribution of the gas stream total temperature field as it passed through a transonic turbine nozzle. Furthermore, there appeared to be a change in area averaged total temperature across the nozzle row. In order to examine these observations, a transonic planar cascade of the exhauster type was constructed at NRC. Tests were carried out at pressure ratios giving nozzle isentropic exit Mach numbers ranging from low subsonic to low supersonic. Wedge probes were used to measure total temperature, total pressure, and flow angles downstream of the nozzle blades. Results of this detailed experimental investigation decisively indicated that the gas stream total temperature at the nozzle exit was highly redistributed. This total temperature separation or energy redistribution strongly depended on Mach number. A maximum temperature separation of 36.0 F occurred just prior to Mach number 1.0. The maximum negatively depressed values of the temperature change differ from those calculated by preliminary analysis and are not just a function of adiabatic wall temperature. An increase of area averaged temperature change was found and was attributed to heat transfer from the ambient surroundings to the planar cascade. Author (CISTI)

ESTIMATION OF AIRCRAFT AERODYNAMIC DERIVATIVES WITH THE TOTAL LEAST SQUARES METHOD [TOTARUISUTO SUKUEA HOU WO MOCHIITA KOUKUUKI NO KUURIK I BIKEISUU NO SUITEI]

Kazuya Masui Apr. 1992 26 p In JAPANESE
(NAL-TR-1150; JTN-93-80483) Avail: CASI HC A03/MF A01

This report describes the Total Least Squares (TLS) Method which estimates unknown linear equation coefficients assuming that both the explanatory variables and the objective variable are affected by measurement errors. This method is one of the generalizations of the conventionally used Least Squares (LS) Method. The concept, algorithm, and characteristics of the TLS method are compared with those of the LS method. It is shown that the TLS method gives the unbiased coefficients and the correct standard deviations of them. In addition, an example of estimating aerodynamic derivatives from flight test data is presented.

HIGH SPEED TRANSITION PREDICTION Final Report

Gediminis Gasperas Aug. 1993 20 p
(Contract NCC2-704)
(NASA-CR-194125; NAS 1.26:194125; MCAT-93-16) Avail: CASI HC A03/MF A01

The main objective of this work period was to develop, maintain and exercise state-of-the-art methods for transition prediction in supersonic flow fields. Basic state and stability codes, acquired during the last work period, were exercised and applied to calculate the properties of various flowfields. The development of a code for the prediction of transition location using a currently novel method (the PSE or Parabolized Stability Equation method), initiated during the last work period and continued during the present work period, was cancelled at mid-year for budgetary reasons. Other activities during this period included the presentation of a paper at the APS meeting in Tallahassee, Florida entitled 'Stability of Two-Dimensional Compressible Boundary Layers', as well as the initiation of a paper co-authored with H. Reed of the Arizona State University entitled 'Stability of Boundary Layers'.

EXPERIMENTAL STUDIES OF VORTEX FLAPS AND VORTEX PLATES. PART 2: 1.15m SPAN 60 DEG DELTA WING

Kenichi Rinoie and John L. Stollery (Cranfield Inst. of Tech., Bedford, England.) Oct. 1992 39 p
(NAL-TR-1180T-Pt-2; JTN-93-80502-Pt-2) Avail: CASI HC A03/MF A01

Low-speed wind tunnel tests were carried out on several vortex flap and vortex plate configurations to assess their benefits. The force and surface pressure measurements were taken using a 1.15 m span, 60 deg delta wing model. Results indicate that the vortex flap deflection angle, which causes the flow to come almost smoothly onto the flap surface without any large separation, shows a much higher lift/drag ratio than the flap deflection angle which forms a leading-edge separation vortex over the flap surface. It was also found that there is no benefit in vortex flap deployment at incidences higher than the stall incidence. The performance of a vortex plate protruding from the leading-edge of the datum delta wing is shown to be comparable to that of the vortex flap. However, when the

vortex plate is used with the vortex flap deflected, these tests showed no benefits. Author (NASDA)

ANALYSIS OF THE HARRIER FOREBODY/INLET DESIGN USING COMPUTATIONAL TECHNIQUES Final Report, 1 Mar. 1991 - 31 Aug. 1993

Chuen-Yen Chow 1993 3 p

(Contract NCC2-714)

(NASA-CR-193616; NAS 1.26:193616) Avail: CASI HC A01/MF A01

Under the support of this Cooperative Agreement, computations of transonic flow past the complex forebody/inlet configuration of the AV-8B Harrier II have been performed. The actual aircraft configuration was measured and its surface and surrounding domain were defined using computational structured grids. The thin-layer Navier-Stokes equations were used to model the flow along with the Chimera embedded multi-grid technique. A fully conservative, alternating direction implicit (ADI), approximately-factored, partially flux-split algorithm was employed to perform the computation. An existing code was altered to conform with the needs of the study, and some special engine face boundary conditions were developed. The algorithm incorporated the Chimera technique and an algebraic turbulence model in order to deal with the embedded multi-grids and viscous governing equations. Comparison with experimental data has yielded good agreement for the simplifications incorporated into the analysis. The aim of the present research was to provide a methodology for the numerical solution of complex, combined external/internal flows. This is the first time-dependent Navier-Stokes solution for a geometry in which the fuselage and inlet share a wall. The results indicate the methodology used here is a viable tool for transonic aircraft modeling. Author

ON THE USE OF THE METHOD OF MATCHED ASYMPTOTIC EXPANSIONS IN PROPELLER AERODYNAMICS AND ACOUSTICS

H. H. Brouwer 9 Aug. 1991 52 p Submitted for publication

(NLR-TP-91307-U; ETN-93-94337) Avail: CASI HC A04/MF A01

The applicability of the method of matched asymptotic expansions to both propeller aerodynamics and acoustics is investigated. The method is applied to a propeller with blades of high aspect ratio, in a uniform axial flow. The first two terms of the inner expansion and the first three terms of the outer expansion are considered. The matching yields an expression for the spanwise distribution of the downwash velocity. However, recasting the analytical expressions into an integral equation, similar to Pradtl lifting line equation for wings, yields results for both aerodynamic and acoustic quantities, which agree well with experimental results. The method, thus, constitutes a practical analysis method for conventional propellers. ESA

CLEBSCH VARIABLE MODEL FOR UNSTEADY, TRANSONIC FLOW; APPLICATION TO 2D AIRFOILS

J. Westland 11 Oct. 1991 85 p

(Contract NIVR-01904N)

(NLR-TP-91387-U; ETN-93-94339) Copyright Avail: CASI HC A05/MF A01

A three dimensional model is derived from the unsteady Euler equations, in which shock generated entropy and vorticity are modeled using a Clebsch variable. This flow model is an extension of full potential theory and is capable of describing unsteady, inviscid, transonic flow with strong shock waves. Its implementation in the existing computer code TULIPS for the calculation of unsteady, transonic flow around a two dimensional airfoil by means of full potential theory is described. Results obtained show good agreement with results obtained from codes based on the Euler equations. ESA

A ROBUST QUASI-SIMULTANEOUS INTERACTION METHOD FOR A FULL POTENTIAL FLOW WITH A BOUNDARY LAYER WITH APPLICATION TO WING/BODY CONFIGURATIONS

A. J. VanderWees and J. VanMuijden 15 Oct. 1991 18 p Presented at the 5th Symposium on Numerical and Physical Aspects of Aerodynamical Flows, Long Beach, CA, 13-15 Jan. 1992

(Contract NIVR-01802N)

(NLR-TP-91397-U; ETN-93-94340) Avail: CASI HC A03/MF A01

A progress report on the system MATRICS (Multicomponent Aircraft Transonic Inviscid Computation System), for the calculation of the three dimensional inviscid transonic potential flow about wing/body configurations, is given. At present, work is in progress to extend MATRICS to take viscous effects into account through coupling with a boundary layer solver. This solver, MATRICS-5, is based on robust calculation methods for the boundary layer, the outer wing flow, and their interaction. MATRICS-5 is intended for (inverse) design purposes. The boundary layer and wake are based on an integral formulation of the unsteady first order boundary layer equations, the inviscid method is the existing MATRICS potential flow solver, and the interaction algorithm is of the quasisimultaneous type. A TECHNIQUE FOR DIRECT MEASUREMENT OF SKIN FRICTION IN SUPERSONIC COMBUSTION FLOW Ph.D. Thesis

Dianne Joan DeTurris 1992 162 p

Avail: Univ. Microfilms Order No. DA9310502

A technique has been developed to directly measure skin friction in the turbulent boundary layer of a three-dimensional supersonic combustion flow. A floating element cantilever beam configuration has been designed to detect two components of the small tangential shear forces created by the flow passing over the non-intrusive floating element. Although skin friction has been measured successfully in cold flow before, this gauge is uniquely designed for testing in high temperature, high heat flux environments. The application which specifically prompted the development of this technique was the propulsion system for the National Aero-Space Plane. An appreciable need exists to determine the skin friction inside the combustor of this scramjet engine, and the three-dimensional, supersonic, reacting flow field is difficult to predict numerically. Gauges were tested in a variety of supersonic combustion facilities, with each combustor requiring customization of the gauge design to the test conditions and geometry of the model wall. Maintaining constant temperature of the strain gages inside the sensor throughout the test cycle is of critical importance, due to their sensitivity to temperature changes. Over the course of the project, many parameters which may affect the measurement were identified and examined individually. Changes were adapted into the design when necessary, including tailoring the design to insure that the floating element temperature remains close to that of the surrounding wall. For this reason, a numerical heat transfer study was undertaken to check that the gauge could be adapted for new test conditions. The output from the gauge during supersonic combustion was found to be repeatable for the same nominal input conditions, and this repeatability was consistent from facility to facility. Results in two-dimensional, supersonic cold flow compare well with predicted flat plate values. Results indicate that C(sub f) is considerably higher in some cases than the corresponding value for a similar Reynolds number flow without combustion. The overall accuracy of the gauge is estimated to be +/- 10 percent. The gauge has made useful measurements in varying flow environments, and shown that its design is adaptable and durable. Author

A THREE-DIMENSIONAL SUPERSONIC TURBULENT BOUNDARY LAYER GENERATED BY AN ISENTROPIC COMPRESSION Ph.D. Thesis

Wolfgang Konrad 1993 200 p

Avail: Univ. Microfilms Order No. DA9311224

An experimental study of a three-dimensional supersonic turbulent boundary layer generated by an isentropic compression is described. The incoming boundary layer was at Mach 2.9 and compressed by a 20 degree curved fin. The experimental data set comprises both mean and fluctuating data. Additionally, data from computations performed by Knight at Rutgers University were available for analysis. Surface flow visualizations, surface static pressures, flowfield surveys of Pitot pressure, yaw angle, and static pressure, and Preston tube measurements were included in the mean data. Hot-wire anemometry with normal and crossed-wires was used to obtain measurements of five of the six components of the Reynolds stress tensor ((-rho-bar)(v')(omego') being the only quantity not measured). The characteristics of the mean flowfield structure were revealed using both

the experimental and the computed mean data. Three different flow regimes were identified: the small crossflow region, the upstream convergence region, and the downstream convergence region. The features of each region were discussed in detail. The turbulence behavior was investigated at one location in each of these identified flow regimes. The mean flowfield behavior was used to explain the turbulence behavior and differences to two-dimensional flows in similar pressure gradients were pointed out. A comparison of the turbulence behavior to that in an adverse pressure gradient with identical initial conditions indicates that the Reynolds shear stress (-rho-bar)(u'v')-bar is significantly reduced due to three-dimensionality and streamline curvature. The results show for the first time in supersonic flow the stabilizing effect of in-plane curvature. Further comparisons with available turbulence data in a 10 degree sharp fin interaction showed a generally similar behavior which was attributed to similar mean flowfield structure. Dissert. Abstr.

CALCULATION OF HYPERSONIC SHOCK STRUCTURE USING FLUX-SPLIT ALGORITHMS

W. M. Eppard and B. Grossman Jul. 1991 17 p

(Grant NAG1-776)

(NASA-CR-194296; NAS 1.26:194296; ICAM-91-07-04) Avail: CASI HC A03/MF A01

There exists an altitude regime in the atmosphere that is within the continuum domain, but wherein the conventional Navier-Stokes equations cease to be accurate. The altitude limits for this so called continuum transition regime depend on vehicle size and speed. Within this regime the thickness of the bow shock wave is no longer negligible when compared to the shock stand-off distance and the peak radiation intensity occurs within the shock wave structure itself. For this reason it is no longer valid to treat the shock wave as a discontinuous jump and it becomes necessary to compute through the shock wave itself. To accurately calculate hypersonic flowfields, the governing equations must be capable of yielding realistic profiles of flow variables throughout the structure of a hypersonic shock wave. The conventional form of the Navier-Stokes equations is restricted to flows with only small departures from translational equilibrium; it is for this reason they do not provide the capability to accurately predict hypersonic shock structure. Calculations in the continuum transition regime, therefore, require the use of governing equations other than Navier-Stokes. Several alternatives to Navier-Stokes are discussed; first for the case of a monatomic gas and then for the case of a diatomic gas where rotational energy must be included. Results are presented for normal shock calculations with argon and nitrogen. Author (revised)

A COMPARISON OF COMPUTATIONAL AND EXPERIMENTAL DATA FOR A SUBSCALE HIGH SPEED PROPULSIVE NOZZLE AT LOW MACH NUMBERS M.S. Thesis

Yonghee Hyun Jun. 1993 164 p

(AD-A266543; AFIT/GAE/ENY/93J-02) Avail: CASI HC A08/MF A02

This computational study of a hypersonic sub-scale nozzle/cowl configuration compares numerical solutions with experimental data for nozzle performance at off design conditions (subsonic through supersonic Mach numbers). A combination of Van Leer and Roe flux-splitting algorithms was used to solve the flow field. The explicit formulation assumed laminar planar flow and the perfect gas equation of state. A validation for the numerical algorithm was accomplished by comparing with experimental data for a variety of cases. Grid refinement, geometry, and operating conditions all influenced the comparison of the experimental and computational data. Generally, as the Mach number and nozzle pressure ratio increased, the consistency between the experimental results showed better agreement, although the computational investigation was performed on the basis of planar, laminar flow. For the different cowl configurations, the results for baseline and -5 degree cowl show a better agreement than the long and +5 degree cowl. DTIC

A COMPUTATIONAL STUDY OF THE BASE REGION FLOW FIELD FOR THE M865 PROJECTILE Final Report, Nov. 1990 - Jun. 1991

Jubaraj Sahu Apr. 1993 33 p Supersedes BRL-IMR-955, Jan. 1991 Original contains color illustrations

(ARL-TR-109) Avail: CASI HC A03/MF A01

Recent firing tests for the M865 projectile have indicated that for reasons unknown, the tracer in the base cavity region does not remain visible during the entire flight. To assist in analyzing this problem, a computational study began to examine the base region flow field for this projectile including the base cavity. Flow computations for this projectile were performed at various supersonic Mach numbers, 2 less than M less than 5 and alpha = 0.0 degree using a time marching Navier-Stokes code. The computed results show sharp changes in the centerline pressure distributions in the base region near M = 3. This unexpected behavior may not be desirable and could be part of the problem. To minimize these pressure oscillations, several proposed configuration changes were made in the afterbody base cavity region and computations were performed for these modified configurations to analyze the effects on the flow field. One of these configurations with a new base cavity shape was found to improve the base region flow field. A modified version of this new base cavity was flight tested and the results revealed some improvement in the visibility of the tracer compared to the original configuration. Author (revised)

CNSFV CODE DEVELOPMENT, VIRTUAL ZONE NAVIER-STOKES COMPUTATIONS OF OSCILLATING CONTROL SURFACES AND COMPUTATIONAL SUPPORT OF THE LAMINAR FLOW SUPERSONIC WIND TUNNEL Final Report

Goetz H. Klopfer May 1993 30 p Original contains color illustrations

(Contract NCC2-616)

(NASA-CR-194259; NAS 1.26:194259; MCAT-93-14) Avail: CASI HC A03/MF A01; 2 functional color pages

The work performed during the past year on this cooperative agreement covered two major areas and two lesser ones. The two major items included further development and validation of the Compressible Navier-Stokes Finite Volume (CNSFV) code and providing computational support for the Laminar Flow Supersonic Wind Tunnel (LFSWT). The two lesser items involve a Navier-Stokes simulation of an oscillating control surface at transonic speeds and improving the basic algorithm used in the CNSFV code for faster convergence rates and more robustness. The work done in all four areas is in support of the High Speed Research Program at NASA Ames Research Center. Author (revised)

FLOW-FIELD INTERFERENCE PRODUCED BY AN ASYMMETRICAL SUPPORT STRUT

M. E. Beyers, H. J. Cai, and P. J. Penna Jan. 1993 45 p

(IAR-AN-75; NCR-32157; CTN-93-60735) Avail: CASI HC A03/MF A01

The interference flow field associated with an asymmetrical strut-mounted aircraft model was studied visually and through floor pressure measurements in a low-speed wind tunnel. The object of the investigation was to elucidate the unsteady interference phenomena which are expected to prevail in oscillatory tests. The conditions under which direct support interference and coupled support/wall interference could occur were explored qualitatively. Static support interference was found to be significant at

incidence angles below approximately 20 deg, and wall interference was found to be significant above this angle. Coupled support/wall interference is expected to be larger in pitch oscillation than in roll oscillation tests. This unsteady interference is expected to peak at intermediate incidence angles near 28 deg. These findings are generally applicable to test installations involving similarly sized models in closed, low-speed wind tunnels. Author (CISTI)

EXPERIMENTAL STUDIES OF VORTEX FLAPS AND VORTEX PLATES. PART 1: 0.53 m SPAN 60 DEG DELTA WING

Kenichi Rinoie Mar. 1992 18 p

(DE93-767969; NAL-TR-1140T; JTN-93-80426) Avail: CASI HC A03/MF A01

Low-speed wind tunnel tests were conducted to investigate the flow around a leading-edge vortex flap at the maximum lift to drag (L/C) condition, and also to measure the performance of an inverted vortex flap and vortex plate. Associated force measurements and flow visualization tests were carried out on a 60 deg delta wing model. Results indicate that the maximum lift to drag ratio for any given flap deflection angle occurs when the flow smoothly comes onto the deflected vortex flap without forming a large leading-edge separation vortex on the flap surface. Use of a vortex plate was found to reduce the drag in comparison to the datum wing, a benefit due to some leading-edge suction acting on the forward facing region between the delta wing and the vortex plate. NUMERICAL SIMULATION OF DYNAMIC STALL OF NACA0012 AIRFOIL OSCILLATING NEAR STATIC STALL ANGLE USING THE NAVIER-STOKES EQUATIONS

Kouji Isogai Mar. 1992 25 p Original contains color illustrations

(DE93-767970; NAL-TR-1141T; JTN-93-80427) Avail: CASI HC A03/MF A01

Numerical simulations were performed using the compressible Navier-Stokes equations to investigate the dynamic stall phenomena of the NACA0012 airfoil oscillating near the static stall angle. The Yee-Harten Total Variation Diminishing (TVD) scheme and the Baldwin-Lomax algebraic turbulence model were employed. The flow pattern, instantaneous pressure distribution, and behavior of the lift and pitching moment during dynamic stall were examined in detail. Computations showed that the major features of the dynamic stall phenomenon were qualitatively well reproduced, e.g., the formation of the leading-edge separation vortex and the behavior of the lift and pitching moment hysteresis loops. However, comparisons of the resultant pitching moment hysteresis loops with experimental data indicated that further research is necessary to obtain a rigorous quantitative prediction of the unsteady aerodynamic forces arising from the massively separated flows. METHODOLOGY OF HYPERSONIC TESTING

1993 339 p Presented at VKI/AEDC Special Course Lecture Series, Rhode Saint Genese, Belgium, 22-26 Feb. 1993

(VKI-LS-1993-03; D/1993/0238/409; ETN-93-94446) Copyright Avail: CASI HC A15/MF A03

An overview of the methods used in hypersonic testing and evaluation is presented and the principles behind those test techniques are explained. Topics covered include an introduction to hypersonic aerodynamics with descriptions of chemical and gas dynamic phenomena associated with hypersonic flight; categories and application of various hypersonic ground test facilities; characterization of facility flow fields; measurement techniques (both intrusive and non intrusive); hypersonic propulsion test principles and facilities; computational techniques and their integration into test programs; ground-test-to-flight data correlation methods; and test program planning. The Lecture Series begins at the introductory level and progressively increases in depth, culminating in a focus on special test and evaluation issues in hypersonics such as boundary layer transition, shock interactions, and electromagnetic wave testing. For individual titles, see N94-14154 through N94-14174.

An introduction to the field of hypersonic testing methodology is given by describing the traditional and future hypersonic system mission requirements. The terminology and phenomenology which is characteristic of hypersonic flow fields, including both the fluid mechanics and physical chemistry characteristics, are addressed. An overview of the hypersonic Test and Evaluation (T and E) requirements, which include the T and E challenges of future systems, the corresponding T and E facilities challenges and shortfalls, and the enabling methodologies and options is given. A survey of some of the fundamental features of hypersonic flow is presented which introduces some of the purely fluid dynamic effects associated with high Mach numbers, as well as thermochemical effects inherent in high speed flows. Concepts such as Mach number independence and Newtonian theory are developed from simple gas dynamic relations. Boundary layer concepts are introduced, and the importance of the energy equation for predicting heating rates is discussed. The effect of entropy swallowing on the boundary layer development is addressed. Viscous interaction effects associated with the thick boundary layers of the high altitude flight regime are also introduced. Thermochemical effects arising due to elevated temperatures encountered in high speed flows are discussed. A method for calculating the equilibrium composition and thermodynamic properties of a reacting gas is described, and examples of the effects of chemical reactions on external and internal flows are presented. The phenomenological aspects of hypersonic flow are emphasized relying on a minimum of mathematical development. ESA

HYPERSONIC PROPULSION CHARACTERIZATION **c07**

Roger Crawford *In* VKI, Methodology of Hypersonic Testing 1993 10 p (For primary document see N94-14153 02-02)

Copyright Avail: CASI HC A02/MF A03

The propulsion cycle options for hypersonic vehicles are summarized including airbreathing, rocket and combinations. Each cycle is characterized by configuration, performance, efficiency and operating envelope. The major components of each propulsion system are identified and evaluated for influence on overall performance. Several combined cycle configurations offer the best propulsion characteristics for the various hypersonic missions from hypersonic transport to single stage to orbit. The unique experimental testing requirements for hypersonic propulsion systems present a significant challenge. ESA

CHARACTERIZATION OF FLOW FIELDS IN HYPERSONIC GROUND TEST FACILITIES **c09**

Albert H. Boudreau *In* VKI, Methodology of Hypersonic Testing 1993 15 p Prepared in cooperation with Arnold Engineering Development Center, Arnold AFS, TN (For primary document see N94-14153 02-02)

Copyright Avail: CASI HC A03/MF A03

The fundamental differences between nonequilibrium encountered in flight and nonequilibrium phenomena encountered in ground test facilities are described. Focus is on facility induced non-equilibrium, describing the gross effects on bodies and the methods now available to characterize such flows. It shows that hypersonic test facilities are inherently difficult to characterize. In the past, many hypersonic facilities were reputed to produce test data of inferior quality when, in fact, it was poor characterization of the flow field principally at fault. With the renaissance in hypersonics at hand, experimentalists face new challenges in characterizing flow fields. The hypersonic test community has developed techniques to accurately

determine free stream conditions. These 'tools of characterization', are described and a standard by which all hypersonic wind tunnels should be compared is suggested. ESA

AERODYNAMIC AND AEROTHERMAL FACILITIES 1: HYPERSONIC WIND TUNNELS **c09**
A. Anderson and R. K. Matthews *In* VKI, Methodology of Hypersonic Testing 1993 13 p Prepared in cooperation with Arnold Engineering Development Center, Arnold AFS, TN (For primary document see N94-14153 02-02)
Copyright Avail: CASI HC A03/MF A03

An overview of hypersonic test facilities, which continue to play a major role in the development of hypersonic vehicles, is given. In the past, ground test facilities were often used to perform configuration parametric studies and/or to develop large data bases. Future testing will emphasize understanding of fluid physics and validation of codes. Computational Fluid Dynamics (CFD) has made great progress in the past two decades, but the marriage of CFD and ground testing is clearly a reality today, and will become even more important in the future as computational and experimental researchers learn how to work together. One of the challenges for the experimentalist is to develop and utilize facilities that simulate hypersonic flight, and to provide the required data precision to validate CFD codes. Fundamental considerations of facilities and simulation issues are reviewed. It is clear that no one facility will meet the wide variety of test objectives; therefore, the test facilities span a range of size, run time, complexity, and operating cost. Representative facilities are described, as well as their test capabilities and their shortfalls. ESA

N94-14159# Calspan Corp., Arnold AFS, TN.
AERODYNAMIC AND AEROTHERMAL FACILITIES 2. PART 1: SHORT-DURATION, HIGH-ENTHALPY FACILITIES **c09**
James R. Maus *In* VKI, Methodology of Hypersonic Testing 1993 15 p Prepared in cooperation with Arnold Engineering Development Center, Arnold AFS, TN (For primary document see N94-14153 02-02)
Copyright Avail: CASI HC A03/MF A03

Short duration facilities primarily used for aerodynamic or aerothermal testing are reviewed. Facilities which have useful run times ranging from a few hundred microseconds to a few hundred milliseconds are considered. The following types of facilities are addressed: arc heated hot shot tunnels, shock heated devices, compression heated wind tunnels, and aeroballistic ranges. Examples of both U.S. and European facilities are given. Principles of operation, facility performance, and strengths and weaknesses of the various types of facilities are emphasized. ESA

AERODYNAMIC AND AEROTHERMAL FACILITIES 2: CONTINUOUS FLOW HIGH ENTHALPY FACILITIES **c09**
Roger Crawford *In* VKI, Methodology of Hypersonic Testing 1993 32 p (For primary document see N94-14153 02-02)
Copyright Avail: CASI HC A03/MF A03

Facilities which provide the thermal equilibrium in structures and propulsion systems required for accurate evaluation of temperature and performance during hypersonic testing are considered. Combustion heated facilities and electric arc heated concepts are reviewed. Also the magnetohydrodynamic augmented arc heated facility performance is presented for very high Mach number simulation above 10. Propulsion system test and simulation requirements include: true enthalpy, correct entropy, free-stream total pressure and clean air for correct combustion kinetics. Exact simulation requires flight test, however each of the high enthalpy facilities reviewed meets most of the requirements for a range of Mach numbers. A set of overheads used in a lecture on arc heater types is annexed. ESA

COMPUTATIONAL TECHNIQUES AND CAPABILITIES **c61**
James R. Maus (Arnold Engineering Development Center, Arnold AFS, TN.) *In* VKI, Methodology of Hypersonic Testing 1993 18 p Prepared in cooperation with Arnold Engineering Development Center, Arnold AFS, TN (For primary document see N94-14153 02-02)
Copyright Avail: CASI HC A03/MF A03

A review of numerical simulation techniques and capabilities, with emphasis on their relationship to the methodology of hypersonic testing, is presented. Flows in the continuum regime are dealt with exclusively and conservation principles and numerical techniques applicable to such flows are presented. The process of modeling complex physics and chemistry that must be included for a realistic treatment of high speed flow is discussed. Options with respect to formulation, discretization strategy, and numerics are presented. The application of some basic numerical algorithms to simplified model equations is undertaken to illustrate some features of the technique. The widening interface between Computational Fluid Dynamics (CFD) and ground testing is also addressed. The use of CFD in planning a ground test program, monitoring the experimental data, and evaluating the test results is discussed. Facility and instrumentation requirements to generate data useful for CFD code validation are indicated. ESA

TEST AND EVALUATION METHODS
R. K. Matthews (Arnold Engineering Development Center, Arnold AFS, TN.) and R. W. Rhudy (Arnold Engineering Development Center, Arnold AFS, TN.) *In* VKI, Methodology of Hypersonic Testing 1993 24 p Prepared in cooperation with Arnold Engineering Development Center, Arnold AFS, TN (For primary document see N94-14153 02-02)
Copyright Avail: CASI HC A03/MF A03

The procedures used in the continuous flow hypersonic tunnels of the AEDC for static stability, pressure, and heat transfer testing are described. Particular emphasis is on heat transfer techniques because of the importance of defining the thermal environment of hypersonic vehicles and because the static stability and pressure techniques are very similar to those used in subsonic and supersonic facilities. Aerothermal methodology includes thermal mapping, discrete gage techniques and gage calibration. Each specific test is described in terms of principle of operation, apparatus, data reduction, and illustrative data. ESA

MATERIALS/STRUCTURES TESTING **c39**
R. K. Matthews (Arnold Engineering Development Center, Arnold AFS, TN.) *In* VKI, Methodology of Hypersonic Testing 1993 12 p Prepared in cooperation with Arnold Engineering Development Center, Arnold AFS, TN (For primary document see N94-14153 02-02)
Copyright Avail: CASI HC A03/MF A03

An overview of the materials/structures test methodology used in the development of hypersonic vehicle components is presented. Focus is on aerothermal methodology and weather/erosion testing. For the latter, testing techniques which evaluate particle impact effects on vehicles operating at supersonic through hypersonic speeds in particle laden environments are described. Such facilities for increasing velocities are: wind tunnels/sleds; arc facilities; aeroballistic ranges. It is noted that it is of particular importance to demonstrate that flight components such as leading edges, cowl lips, and structural panels will survive the aerothermal flight environment. Specific components can experience very high heating rates and surface temperatures from 1100 to 1950 C. ESA

HYPERSONIC FLOW FIELD MEASUREMENTS: INTRUSIVE
R. K. Matthews *In* VKI, Methodology of Hypersonic Testing 1993
13 p Prepared in cooperation with Arnold Engineering Development Center, Arnold AFS, TN (For primary document see N94-14153 02-02)
Copyright Avail: CASI HC A03/MF A03

'Intrusive' flow field measurements, ones that require a probe or other device to be inserted into the flow, are discussed. In general, these intrusive techniques are currently viewed as inferior to the more popular nonintrusive techniques. However, it should be remembered that in general these intrusive techniques have evolved over several decades while the flow field experience of nonintrusive techniques is relatively limited. Included in the intrusive classification are pitot tubes, total temperature probes, Mach/angularity probes, static pressure devices, hot wire anemometers, and flow visualization methods (vapor screen, and oil flow techniques). Each of these methods is considered. Within limits, each of these techniques can provide very useful data for the aerodynamicist. ESA

The differences revealed by initial space flights between preflight aerodynamic predictions and actual flight data, were investigated. For the Space Shuttle these differences were notable for longitudinal trim during high speed reentry. To investigate these differences, several computer codes were applied to a modified Space Shuttle Orbiter to determine aerodynamic parameters over a wide range of conditions. Computations were carried out for wind tunnel conditions and flight conditions to assess Mach number, real gas, and viscous effects on the reentry aerodynamics of the orbiter. Based on the computational fluid dynamics results and a semiempirical analysis of viscous effects, an aerodynamic model for the orbiter was developed to extrapolate wind tunnel data for the Space Shuttle Orbiter to flight conditions. ESA

The prediction of the boundary layer transition Reynolds number for the design of hypersonic vehicles is considered. The boundary layer state (laminar or turbulent) that approaches the vehicle control surfaces can significantly affect the control surface effectiveness. In addition, the heating rates associated with turbulent boundary layers are often ten times higher than those of laminar boundary layers. Unfortunately, the methodology to predict transition has eluded the aerodynamicist for over three decades, and there are still many unanswered questions. Many parameters that affect transition are considered and numerous references for those who are interested in specializing in this topic are provided. It is emphasized that during wind tunnel testing it is very important to know the boundary layer state. Typically, heat transfer distributions can provide this information; however, it is often necessary to artificially trip the flow to induce a turbulent boundary layer. The methodology of using trip spheres is discussed, and illustrative data are presented. ESA

ELECTROMAGNETIC WAVE TEST **c32**
R. K. Matthews and S. A. Stepanek *In* VKI, Methodology of Hypersonic Testing 1993 7 p Prepared in cooperation with Arnold Engineering Development Center, Arnold AFS, TN (For primary document see N94-14153 02-02)
Copyright Avail: CASI HC A02/MF A03

Electromagnetic wave testing, which represents a relatively new test technique that involves the union of several disciplines (aerothermodynamics, electromagnetics, materials/structures, and advanced diagnostics) is introduced. The essence of this new technique deals with the transmission and possible distortion of electromagnetic waves (RF or IR) as they pass through the bow shock, flow field, and electromagnetic window of a missile flying at hypersonic speeds. Variations in gas density along the optical path can cause significant distortion of the electromagnetic waves and, therefore the missile seeker system may not effectively track the target. Two specific test techniques are described. The first example deals with the combining of a wind tunnel and an RF range while the second example discusses the complexities of evaluating IR seeker system performance. ESA

PROPULSION INTEGRATION **c07**
Roger Crawford *In* VKI, Methodology of Hypersonic Testing 1993 11 p (For primary document see N94-14153 02-02)
Copyright Avail: CASI HC A03/MF A03

The airframe-propulsion system integration of hypersonic vehicles is discussed considering the influences and problems of each of the contributing factors: inlet integration, combustion integration, nozzle integration, thermal management, and control system integration. It is noted that very high levels of efficiency in inlet, combustor and nozzle performance are required to assure net positive propulsive force in the integrated system. The higher the flight Mach number, the more difficult this integration task becomes. The inlet and nozzle integration requirements are evaluated for performance, stability and control influence on the flight vehicle. Combustor performance, fuel flow requirements and cooling loads are coupled by flight vehicle thermal management constraints. Low volumetric efficiency of the high energy density cryogenic fuels impacts the vehicle configuration due to the large fuel tank size. Thus the highly integrated hypersonic flight vehicle configuration is dominated by the propulsion system. ESA

MIXING NOISE REDUCTION FOR RECTANGULAR SUPERSONIC JETS BY NOZZLE SHAPING AND INDUCED SCREECH MIXING
Edward J. Rice and Ganesh Raman (Sverdrup Technology, Inc., Brook Park, OH.) Oct. 1993 12 p Proposed for presentation at the 15th AIAA Aeroacoustics Conference, Long Beach, CA, 25-27 Oct. 1993; sponsored by AIAA
(Contract NAS3-25266; RTOP 537-02-22)
(NASA-TM-106364; E-8165; NAS 1.15:106364; AIAA Paper 93-4322)
Avail: CASI HC A03/MF A01

Two methods of mixing noise modification were studied for supersonic jets flowing from rectangular nozzles with an aspect ratio of about five and a small dimension of about 1.4 cm. The first involves nozzle geometry variation using either single (unsymmetrical) or double bevelled (symmetrical) thirty degree cutbacks of the nozzle exit. Both converging (C) and converging-diverging (C-D) versions were tested. The double bevelled C-D nozzle produced a jet mixing noise reduction of about 4 dB compared to a standard rectangular C-D nozzle. In addition all bevelled nozzles produced an upstream shift in peak mixing noise which is conducive to improved attenuation when the nozzle is used in an acoustically treated duct. A large increase in high frequency noise also occurred near the plane of the nozzle exit. Because of near normal incidence, this noise can be easily attenuated with wall treatment. The second approach uses paddles inserted on the edge of the two sides of the jet to induce screech and greatly enhance the jet mixing. Although screech and mixing noise levels are increased, the enhanced mixing moves the source locations upstream and may make an enclosed system more amenable to noise reduction using wall acoustic treatment. DOMAIN CONNECTIVITY AMONG SYSTEMS OF OVERSET GRIDS Progress Report
Robert L. Meakin 26 Jul. 1993 10 p
(Contract NCC2-783)
(NASA-CR-193390; NAS 1.26:193390) Avail: CASI HC A02/MF A01

This progress report describes research performed to achieve algorithmic improvements in the use of overset grids for the computation of unsteady flowfields about geometrically complex and moving component configurations. A hole-map computational method is detailed that reduces computational demand and corresponding demand on human resources. Results indicate that the method is both efficient and flexible for use in complex simulation cases. Tests were performed on shuttle orbiter/external tank, wing/store, and V-22 tilt-rotor configurations. The number of simulated points and the corresponding time on a SGI 4D-210 workstation are presented. CASI

(Grant NAG1-1139)
(NASA-CR-194523; NAS 1.26:194523) Avail: CASI HC A05/MF A02

This report addresses and clarifies a number of issues related to the Matched Asymptotic Expansion (MAE) analysis of skip trajectories, or any class of problems that give rise to inner layers that are not associated directly with satisfying boundary conditions. The procedure for matching inner and outer solutions, and using the composite solution to satisfy boundary conditions is developed and rigorously followed to obtain a set of algebraic equations for the problem of inclination change with minimum energy loss. A detailed evaluation of the zeroth order guidance algorithm for aeroassisted orbit transfer is performed. It is shown that by exploiting the structure of the MAE solution procedure, the original problem, which requires the solution of a set of 20 implicit algebraic equations, can be reduced to a problem of 6 implicit equations in 6 unknowns. A solution that is near optimal, requires a minimum of computation, and thus can be implemented in real time and on-board the vehicle, has been obtained. Guidance law implementation entails treating the current state as a new initial state and repetitively solving the zeroth order MAE problem to obtain the feedback controls. Finally, a general procedure is developed for constructing a MAE solution up to first order, of the Hamilton-Jacobi-Bellman equation based on the method of characteristics. The development is valid for a class of perturbation problems whose solution exhibits two-time-scale behavior. A regular expansion for problems of this type is shown to be inappropriate since it is not valid over a narrow range of the independent variable. That is, it is not uniformly valid. Of particular interest here is the manner in which matching and boundary conditions are enforced when the expansion is carried out to first order. Two cases are distinguished-one where the left boundary condition coincides with, or lies to the right of, the singular region, and another one where the left boundary condition lies to the left of the singular region. A simple example is used to illustrate the procedure where the obtained solution is uniformly valid to O(Epsilon(exp 2)). The potential application of this procedure to aeroassisted plane change is also described and partially evaluated. Author (revised)

AN EXPERIMENTAL STUDY OF A TURBULENT BOUNDARY LAYER IN THE TRAILING EDGE REGION OF A CURCULATION-CONTROL AIRFOIL Progress Report, 1 Oct. 1992 - 30 Jun. 1993
Jeff Brown 12 Oct. 1993 6 p
(Contract NCC2-545)
(NASA-CR-194522; NAS 1.26:194522) Avail: CASI HC A02/MF A01

This report discusses progress made on NASA Cooperative Agreement NCC2-545, 'An Experimental Study of a Turbulent Boundary Layer in the Trailing-Edge Region of a Circulation-Control Airfoil,' during the period 1 Oct. 1992 - 30 Jun. 1993. The study, being conducted by Jeff Brown of the Eloret Institute, in conjunction with the Experimental Fluid Dynamics Branch at NASA Ames (Dennis Johnson, technical monitor), features 2-component laser Doppler velocimeter (LDV) measurements in the trailing edge and wake regions of a generic circulation-control airfoil model. The

final experimental phase of the study will be carried out in the Ames High Reynolds Number Channel II (HRC2) transonic blow-down facility. During the 9-month period covered by this report, important data were acquired using the near-wall laser Doppler velocimeter (LDV) whose development has been described in previous reports. These data point strongly to the viability of this new technique for measuring the full Reynolds Stress Tensor in 3D flows. Author (revised)

INTRA-BLADE QUANTITATIVE TRANSONIC FLOW MEASUREMENTS AT THE DRA PYESTOCK ISENTROPIC LIGHT PISTON FACILITY USING PIV (PARTICLE IMAGE VELOCIMETRY)

K. S. Chana, I. W. Matthews, P. J. Bryanston-Cross (Warwick Univ., Coventry, England.), and M. Funes-Gallanzi (Warwick Univ., Coventry, England.) 15 Dec. 1992 16 p Presented at the 11th International Symposium on Measuring Techniques for Transonic and Supersonic Flows in Cascades and Turbomachines, Munich, Germany, 14-15 Sep. 1992 Original contains color illustrations

(RAE-TM-Aero/Prop-21; BR316329; ETN-93-94497) Copyright Avail: CASI HC A03/MF A01

Measurements made with the quantitative whole field flow visualization technique of Particle Image Velocimetry (PIV) in a transonic annular cascade are addressed. The measurements, which provided an instantaneous quantitative whole field visualization of unsteady region of flow, were compared with a full viscous prediction. The Isentropic Light Piston Facility used to make the measurements is described. The PIV techniques used are discussed along with the following: optical laser firing system; Nd/YAG pulse laser; diffraction limited optics; beam propagation optics; PIV optical probe design; imaging system; data processing; and preprocessing and data analysis. SIMULATION OF HYPERSONIC, REACTING FLOW AROUND REENTRY BODIES: COMPARISONS OF NUMERICAL AND EXPERIMENTAL RESULTS

C. Mundt, R. R. Boyce (Australian National Univ., Canberra.), and E. H. Hirschel Sep. 1992 18 p Presented at DGLR-Jahrestagung 1992, Bremen, Germany, 29 Sep. - 2 Oct. 1992

(MBB-LME-211-S-PUB-507; DGLR-92-03-108; ETN-93-94196) Copyright Avail: CASI HC A03/MF A01

Results of an ongoing validation project for hypersonic flow prediction, which involved both numerical methods and experimental facilities, are presented. The flow was simulated numerically by solving the Euler and the second order boundary layer equations. For the description of the thermodynamic and chemical behavior of the test gases, different models were used depending on the state of the flow around the test body. The experimental facility used was the free piston hypervelocity shock tunnel T3, capable of simulating the real gas chemical effects encountered in reentry. Techniques to retrieve information about the flows range from surface measurements through bulk flow visualizations to single point optical flow diagnostics. The general strategy for the comparison is described and the results obtained for different parameters and different test gases are compared critically. A hyperboloid is chosen to be the test body. The results of the comparison provide confidence in both the numerical method and the modeling of high temperature physical and chemical effects. ESA

NEW VORTEX DYNAMICS METHODS FOR ROTOR FREE WAKE ANALYSIS Final Report, 15 May 1988 - 14 May 1991

Donald B. Bliss May 1993 52 p

(Contract DAAL03-88-K-0062)

(AD-A266656; ARO-25747.1-EG) Avail: CASI HC A04/MF A01

This report summarizes recent work on rotorcraft aerodynamics involving novel methods for rotor free wake calculations. A new method called Analytical/Numerical Matching (ANM) was developed. ANM is a hybrid analytical and numerical method that achieves accurate results by combining a low resolution numerical solution with a high resolution analytical solution. Although originally developed for vortex dynamics, ANM has proven to be of a general nature. The application of ANM to the rotor wake problem provides accurate answers with a significant reduction in computation time. The use of ANM introduces the opportunity to develop new solution strategies, including Far-Field Linearization and Periodic Inversion. These methods afford the means to obtain accurate solutions Over the entire flight regime. Work involving applications of ANM has also led to a scheme that represents vortex filament dynamics by a hierarchy of nested problems of varying resolution joined by matching solutions. This approach, called ANM with Pyramiding (ANM/P), has reduced calculation times by more than a factor of twenty in some sample problems. DTIC

INTERACTION OF TWO GLANCING, CROSSING SHOCK WAVES WITH A TURBULENT BOUNDARY-LAYER AT VARIOUS MACH NUMBERS

Warren R. Hingst and Kevin E. Williams (Washington Univ., Seattle.) Sep. 1991 97 p

(RTOP 505-62-31)

(NASA-TM-103740; E-6566; NAS 1.15:103740) Avail: CASI HC A05/MF A02

A preliminary experimental investigation was conducted to study two crossing, glancing shock waves of equal strengths, interacting with the boundary-layer developed on a supersonic wind tunnel wall. This study was performed at several Mach numbers between 2.5 and 4.0. The shock waves were created by fins (shock generators), spanning the tunnel test section, that were set at angles varying from 4 to 12 degrees. The data acquired are wall static pressure measurements, and qualitative information in the form of oil flow and schlieren visualizations. The principle aim is two-fold. First, a fundamental understanding of the physics underlying this flow phenomena is desired. Also, a comprehensive data set is needed for computational fluid dynamic code validation. Results indicate that for small shock generator angles, the boundary-layer remains attached throughout the flow field. However, with increasing shock strengths (increasing generator angles), boundary layer separation does occur and becomes progressively more severe as the generator angles are increased further. The location of the separation, which starts well downstream of the shock crossing point, moves upstream as shock strengths are increased. At the highest generator angles, the separation appears to begin coincident with the generator leading edges and engulfs most of the area between the generators. This phenomena occurs very near the 'unstart' limit for the generators. The wall pressures at the lower generator angles are nominally consistent with the flow geometries (i.e. shock patterns) although significantly affected by the boundary-layer upstream influence. As separation occurs, the wall pressures exhibit a gradient that is mainly axial in direction in the vicinity of the separation. At the limiting conditions the wall pressure gradients are primarily in the axial direction throughout. Author (revised)

FREE-WAKE COMPUTATION OF HELICOPTER ROTOR FLOWFIELD FOR GENERAL FLIGHT REGIMES Final Report, 1 Oct. 1989 - 30 Sep. 1992

Krishna Ramachandran, John Steinhoff, and Wenren Yonghu 30 Mar. 1993 79 p

(Contract DAAL03-89-C-0027)

(AD-A266692; ARO-25623.4-EG-S) Avail: CASI HC A05/MF A01

A CFD based computer code, HELIX 2 has been developed for computing helicopter rotor flowfield in hover and in forward flight. In order to predict the vibratory airloads in forward flight and the performance in hover the effect of shed wake has to be accurately accounted for. This has been accomplished by an unique vorticity embedding procedure. The wake is convected in a Lagrangian sense and does not suffer from numerical dissipation. The effect of this convected wake is included in the Eulerian using Clebsch representation. The unsteady full potential equation is solved in the Eulerian grid with the embedded vortical velocity accounting for the influence of wake. The wake evolves as a part of the solution. Dynamic grid modifications are performed at each time step to account for blade motion and deformation. These modifications are confined to regions near the blade using suitable blending functions. In addition a vorticity confinement method is developed which involves adding a term to the momentum conservation equation of fluid dynamics. This modification is very useful in the numerical solution of flow problems involving vortical regions. The Euler equations solved with this extra term can convect vortices without Numerical dissipation. DTIC

A NEW TREATMENT OF PERIODIC SYSTEMS WITH APPLICATIONS TO HELICOPTER ROTOR BLADE DYNAMICS Final Report, 15 Sep. 1989 - 31 Mar. 1993
Subbash C. Sinha 28 May 1993 9 p
(Contract DAAL03-89-K-0172)
(AD-A266770; ARO-26061.15-EG) Avail: CASI HC A02/MF A01

A new solution technique for general periodic systems encountered in many mechanical systems including the helicopter rotor-blade dynamics has been developed. In this technique, the state transition matrices (STM) of periodic systems are obtained in terms of the shifted Chebyshev polynomials of first and second kind. Due to the excellent convergence properties of Chebyshev polynomials, the approach is found to be super efficient in terms of the CPU time with accuracy level comparable to any higher order numerical algorithms such as Runge-Kutta, Adams-Mouton, etc. The technique is suitable for both numerical and symbolic implementations. The method can be used in a variety of applications such as stability of linear and nonlinear periodic systems, response calculations of linear and nonlinear periodic systems, design of control systems for periodic systems, direct determination of periodic orbits of nonlinear systems and nonlinear analysis of periodic systems in stable, center and unstable manifolds. Case studies corresponding to each of these applications have been reported. Apart from the above mentioned utilities, the technique has resulted in a very practical procedure in obtaining the well-known Liapunov-Floquet (L-F) Transformation matrix which allows one to design a control system in the time-invariant domain. Currently, the research efforts are directed toward utilizing the L-F transformation matrix for various other problems such as order reduction, bifurcation analysis and nonlinear control design strategies for periodic systems. In the following, a short enumeration of the achievements of the project is presented.

CENTER OF EXCELLENCE IN ROTARY WING TECHNOLOGY Final Report
O. Bauchau, Crespo M. daSilva, M. Darlow, P. Hajela, and E. Krempl 1 Apr. 1993 207 p
(Contract DAAL03-88-C-0004)
(AD-A266655; ARO-25462.13-EG-RW) Avail: CASI HC A10/MF A03

The activities of a Center of Excellence in Rotary Wing Technology at Rensselaer Polytechnic Institute under a second, continuation five year contract with the U.S. Army Research Office are reported here. The activities include the following: measures taken to revise and update comprehensive and in-depth curricula at advanced levels in rotorcraft technology; attract and retain outstanding young people in these programs; perform basic research at the leading edge of technology in structures, structural dynamics, unsteady aerodynamics, and aeroelasticity disciplines as applied to rotorcraft; and accomplishing technology transfer to the rotorcraft community beyond the Rensselaer campus. Descriptions, references, and statistics are provided to allow assessment of the extent to which these goals have been realized.

DEVELOPMENT OF EXPERIMENTAL DEMONSTRATION PROCESSES FOR LAMINAR-TURBULENT FLOW STATES AT WING PROFILES IN FREE FLIGHT Final Report [ENTWICKLUNG EXPERIMENTELLER NACHWEISVERFAHREN FUER LAMINAR-TURBULENTE STROEMUNGSZUSTAENDE AN TRAGFLUEGELPROLIFEN IM FREIFLUG. ABSCHLUSSBERICHT]
P. Mirow and W. Nitsche 1993 40 p In GERMAN Sponsored by BMFT
(ILR-Mitt-280(1993); ETN-93-94381) Avail: CASI HC A03/MF A01

Measurement techniques for industrial laminar wing experiments on a Grob 109B aircraft were developed and tested; two perturbation free surface measuring processes, piezoarray technique and CPM3 (Computational Preston tube Method), and an onboard supported data acquisition system are presented; CHM2 (Computational Hot-wire Method) was equally used for measuring wall shear stresses and torsional stress variations. CPM3 method was used for determination of local wall friction; power spectrum, time signals, and adaptation factors were obtained with piezoelectric foils, which proved to be very efficient for analysis of flow instabilities, but the method is found to be very expensive because of the necessity of multisensor arrays. It is concluded that a combination of both processes seems to be optimal for flight tests.

A NEW LAGRANGIAN METHOD FOR THREE-DIMENSIONAL STEADY SUPERSONIC FLOWS
Ching-Yuen Loh and Meng-Sing Liou Sep. 1993 39 p
(RTOP 505-62-52)
(NASA-TM-106068; E-7673; NAS 1.15:106068) Avail: CASI HC A03/MF A01

In this report, the new Lagrangian method introduced by Loh and Hui is extended for three-dimensional, steady supersonic flow computation. The derivation of the conservation form and the solution of the local Riemann solver using the Godunov and the high-resolution TVD (total variation diminished) scheme is presented. This new approach is accurate and robust, capable of handling complicated geometry and interactions between discontinuous waves. Test problems show that the extended Lagrangian method retains all the advantages of the two-dimensional method (e.g., crisp resolution of a slip-surface (contact discontinuity) and automatic grid generation). In this report, we also suggest a novel three dimensional Riemann problem in which interesting and intricate flow features are present.

COGNITIVE ENGINEERING IN AEROSPACE APPLICATION: PILOT INTERACTION WITH COCKPIT AUTOMATION

Nadine R. Sarter and David D. Woods Aug. 1993 71 p
(Contract NCC2-592)
(NASA-CR-177617; A-93108; NAS 1.26:177617) Avail: CASI HC A04/MF A01

Because of recent incidents involving glass-cockpit aircraft, there is growing concern with cockpit automation and its potential effects on pilot performance. However, little is known about the nature and causes of problems that arise in pilot-automation interaction. The results of two studies that provide converging, complementary data on pilots' difficulties with understanding and operating one of the core systems of cockpit automation, the Flight Management System (FMS) is reported. A survey asking pilots to describe specific incidents with the FMS and observations of pilots undergoing transition training to a glass cockpit aircraft served as vehicles to gather a corpus on the nature and variety of FMS-related problems. The results of both studies indicate that pilots become proficient in standard FMS operations through ground training and subsequent line experience. But even with considerable line experience, they still have difficulties tracking FMS status and behavior in certain flight contexts, and they show gaps in their understanding of the functional structure of the system. The results suggest that design-related factors such as opaque interfaces contribute to these difficulties which can affect pilots' situation awareness. The results of this research are relevant for both the design of cockpit automation and the development of training curricula specifically tailored to the needs of glass cockpits. Author (revised)

SMART SKIN TECHNOLOGY DEVELOPMENT FOR MEASURING ICE ACCRETION, STALL, AND HIGH AOA AIRCRAFT PERFORMANCE. PART 1: CAPACITIVE ICE DETECTOR DEVELOPMENT Final Technical Report
Daniel A. Pruzan, Ateen A. Khatkhate, Joseph J. Gerardi, and Gail A. Hickman 23 Apr. 1993 86 p Revised
(Contract NAS3-25966; SBIR-03.01-0533)
(NASA-CR-194252; NAS 1.26:194252; Rept-93D-03-0423-Pt-1) Avail: CASI HC A05/MF A01

A reliable way to detect and measure ice accretion during flight is required to reduce the hazards of icing currently threatening present day aircraft. Many of the sensors used for this purpose are invasive (probe) sensors which must be placed in areas of the airframe where ice does not naturally form. Due to the difference in capture efficiency of the exposed surface, difficulties result in correlating the ice accretion on the probe to what is happening on a number of vastly different airfoil sections. Most flush mounted sensors in use must be integrated into the aircraft surface by cutting or drilling the aircraft surface. An alternate type of ice detector which is based on a NASA patent is currently being investigated at Innovative Dynamics, Inc. (IDI). Results of the investigation into the performance of different capacitive type sensor designs, both rigid as well as elastic, are presented. Author (revised)

OPTIMAL LATERAL ESCAPE MANEUVERS FOR MICROBURST ENCOUNTERS DURING FINAL APPROACH
H. G. Visser Jul. 1992 44 p
(LR-691; ETN-93-94416) Avail: CASI HC A03/MF A01

The control and optimization of lateral escape trajectories in a microburst wind field for an aircraft on final approach is discussed. The performance index being minimized is the peak value of altitude drop. The characteristics of open loop extremal solutions for different locations of the microburst were calculated. If a sufficiently large bank angle limit is specified and the center of the microburst is not too far offset from the centerline extension of the approach runway, typically three trajectories can be found that satisfy the first order necessary conditions of optimality. The results bear out that trajectories that feature lateral maneuvering to turn the aircraft away from the microburst center, offer a significant improvement in the escape capability of the aircraft in comparison to a trajectory that passes through the center. In contrast to nonturning escape maneuvers, lateral escape maneuvers often exhibit an initial climb, rather than a descent. It is conjectured that this behavior is a result of optimal energy management. Efforts to develop a closed loop (feedback) guidance scheme that closely approximates the open loop trajectories are described. ESA

THE INTERNATIONAL REGULATION OF AIR TRANSPORT: CHANGING REGIMES AND PRICE EFFECTS Ph.D. Thesis
Martin Elliot Dresner Jul. 1989 340 p
(ISBN-0-315-55958-6; CTN-93-60728) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

Regulatory changes in the international air transport industry are traced from World War II to the present. A modified version of hegemonic stability theory was formulated and applied to the industry to explain the developments. Additional domestic political and market structural variables were introduced to arrive at a more comprehensive model of regime change. The comprehensive model added significantly to the explanation of regime developments. Finally, the model was used to predict future developments in the industry. It was predicted that there was still political credit to be gained from air services liberalization in developed areas of the world and that regulations in these areas are likely to be liberalized. A model was also developed to explain price differences on international air routes. Major assumptions were that airlines competing on liberalized air routes engaged in Bertrand pricing behavior, while carriers on non-liberal routes colluded to set prices. Several empirical versions of the model were used to test for price effects that arose from liberal agreements. The liberal agreements were found to contribute to lower discount fares significantly but not necessarily to lower normal fares. The findings were consistent with the use of greater price discrimination under the liberal bilateral agreements. Author (CISTI)

[ACTIVITIES REPORT OF THE FEDERAL ADMINISTRATION FOR FLIGHT SAFETY (GERMANY)] Annual Report, 1991 [JAHRESBERICHT '91 DER BUNDESANSTALT FUER FLUGSICHERUNG]
1992 53 p In GERMAN
(ETN-93-94208) Copyright Avail: CASI HC A04/MF A01

Statistical information, technological advances and measures taken by German administration in the flight safety area are presented. The role of cooperation between transportation and defense departments was outlined. Air traffic service routes were created or modified in order to remedy to traffic increase. Standard flight safety processes were introduced at former East Germany airports. Safety management services for Netherlands, Belgium and Federal Republic of Germany decided the integration of their existing air traffic control system in a common project for optimization of radar information use, by means of radar data interchange network. Safety improvements, obtained with instrument and microwave ranging systems and modifications in information and data transfer facilities were reported. Design phase of a monopulse secondary radar subsystem in the framework of the radar modernization program was achieved by introducing critical design review concept. An integration test between sensor data processor and radar message conversion and distribution equipment was performed. Feasibility of a short term conflict alert system was examined and the American en route automated radar tracking system was chosen. A departure coordination system for reduction of coordination cost between toward and approach control and area control center workstations was implemented at the Frankfurt airport. A weather data and information visualization system with light waveguide transmission was implemented at new Munich airport. Statistical information about air traffic in Germany is given. ESA

WIDEBODY CABIN WATER SPRAY OPTIMIZATION TESTS
Timothy R. Marker Aug. 1993 47 p Original contains color illustrations
(DOT/FAA/CT-TN93/29) Avail: CASI HC A03/MF A01

Nine full-scale tests were conducted in a modified DC-10 test article as part of an aircraft cabin water spray optimization study. The purpose of the study was to test several spray configurations by varying the orientation of the nozzles, the flow rate, and the quantity of water sprayed, while keeping the fire conditions constant, in an attempt to minimize the amount of water required to effectively suppress a postcrash aircraft fire and improve occupant survivability. The tests were used to validate optimization tests previously conducted in the narrowbody 707 test article. The initial test series employed a full-zone spray system, extending across the width of

the fuselage, consisting of 7 zones, each containing 12 nozzles. A thermocouple was centrally mounted at ceiling height in each of the 8 foot long zones, allowing for the activation of a particular zone when the temperature reached a pre-determined value. A second series of tests were run in which the original zones were divided in half, producing 5 zones on either side of the fuselage centerline for a total of 10. Each of the 10 zones contained 6 nozzles. The survival time was extended between 41 and 103 seconds, depending on zone configuration, discharge activation temperature, and cabin location. Author

A MODEL FOR FUEL FIRE DURATION AND APPLICATION TO THE B-1B BOMBER
D. E. Magnoli 15 Dec. 1992 67 p
(Contract W-7405-eng-48)
(DE93-013000; UCRL-ID-112576) Avail: CASI HC A04/MF A01 (US Sales Only)

A current national priority is ensuring that nuclear weapons remain safe (i.e., that they have a very low probability of plutonium dispersal) even when exposed to abnormal environments. In order to be able to quantify the probability of plutonium release, it is imperative to understand the abnormal environments to which weapons might be subjected. One type of abnormal environment arises from an accidental fuel fire. This report deals with the environment created by exposure to fire and represents an initial effort to quantify fire durations and to describe fire duration statistically. Section 1 of the report documents the model developed to describe the duration of fuel fires on aircraft, where the source of the fuel is leaking fuel tanks. Section 2 examines the question of spreading to determine under what conditions a fire due to a leak in one fuel tank will spread to another. A later report will describe a first-cut effort to correlate the fires examined here with a temperature distribution. DOE

THE INFLUENCE OF ATC MESSAGE LENGTH AND TIMING ON PILOT COMMUNICATION
Daniel Morrow and Michelle Rodvold (San Jose State Univ., CA.) Aug. 1993 24 p
(Contract NAS2-13210)
(NASA-CR-177621; A-93115; NAS 1.26:177621) Avail: CASI HC A03/MF A01

Pilot-controller communication is critical to safe and efficient flight. It is often a challenging component of piloting, which is reflected in the number of incidents and accidents involving miscommunication. Our previous field study identified communication problems that disrupt routine communication between pilots and controllers. The present part-task simulation study followed up the field results with a more controlled investigation of communication problems. Pilots flew a simulation in which they were frequently vectored by Air Traffic Control (ATC), requiring intensive communication with the controller. While flying, pilots also performed a secondary visual monitoring task. We examined the influence of message length (one message with four commands vs. two messages with two commands each) and noncommunication workload on communication accuracy and length. Longer ATC messages appeared to overload pilot working memory, resulting in more incorrect or partial readbacks, as well as more requests to repeat the message. The timing between the two short messages also influenced communication. The second message interfered with memory for or response to the first short message when it was delivered too soon after the first message. Performing the secondary monitoring task did not influence communication. Instead, communication reduced monitoring accuracy. Author

INVESTIGATION FOR IMPROVING GLOBAL POSITIONING SYSTEM (GPS) ORBITS USING A DISCRETE SEQUENTIAL ESTIMATOR AND STOCHASTIC MODELS OF SELECTED PHYSICAL PROCESSES Annual Report
Clyde C. Goad and C. David Chadwell Aug. 1993 34 p
(Grant NAG5-2041; RF Proj. 760126/72687)
(NASA-CR-194167; NAS 1.26:194167) Avail: CASI HC A03/MF A01

GEODYNII is a conventional batch least-squares differential corrector computer program with deterministic models of the physical environment. Conventional algorithms were used to process differenced phase and pseudorange data to determine eight-day Global Positioning system (GPS) orbits with several meter accuracy. However, random physical processes drive the errors whose magnitudes prevent improving the GPS orbit accuracy. To improve the orbit accuracy, these random processes should be modeled stochastically. The conventional batch least-squares algorithm cannot accommodate stochastic models, only a stochastic estimation algorithm is suitable, such as a sequential filter/smoother. Also, GEODYNII cannot currently model the correlation among data values. Differenced pseudorange, and especially differenced phase, are precise data types that can be used to improve the GPS orbit precision. To overcome these limitations and improve the accuracy of GPS orbits computed using GEODYNII, we proposed to develop a sequential stochastic filter/smoother processor by using GEODYNII as a type of trajectory preprocessor. Our proposed processor is now completed. It contains a correlated double difference range processing capability, first order Gauss Markov models for the solar radiation pressure scale coefficient and y-bias acceleration, and a random walk model for the tropospheric refraction correction. The development approach was to interface the standard GEODYNII output files (measurement partials and variationals) with software modules containing the stochastic estimator, the stochastic models, and a double differenced phase range processing routine. Thus, no modifications to the original GEODYNII software were required. A schematic of the development is shown. The observational data are edited in the preprocessor and the data are passed to GEODYNII as one of its standard data types. A reference orbit is determined using GEODYNII as a batch least-squares processor and the GEODYNII measurement partial (FTN90) and variational (FTN80, V-matrix) files are generated. These two files along with a control statement file and a satellite identification and mass file are passed to the filter/smoother to estimate time-varying parameter states at each epoch, improved satellite initial elements, and improved estimates of constant parameters. ERROR ANALYSIS OF REAL TIME AND POST PROCESSED OR BIT DETERMINATION OF GFO USING GPS TRACKING Final Report
William S. Schreiner 5 Oct. 1991 10 p
(Grant NGT-50623)
(NASA-CR-193646; NAS 1.26:193646; CU-1536481) Avail: CASI HC A02/MF A01

The goal of the Navy's GEOSAT Follow-On (GFO) mission is to map the topography of the world's oceans in both real time (operational) and post processed modes. Currently, the best candidate for supplying the required orbit accuracy is the Global Positioning System (GPS). The purpose of this fellowship was to determine the expected orbit accuracy for GFO in both the real time and post-processed modes when using GPS tracking. This report presents the work completed through the ending date of the fellowship. Derived from text

FLIGHT EVALUATIONS OF APPROACH/LANDING NAVIGATION SENSOR SYSTEMS: SUMMARY OF 1990 FLIGHT EXPERIMENTS [MLS TOU KOUHOUKEI HIKOU JIKKEN: HEIZEI 2 NENDO NO JIKKEN GAIYOU]

Kouichi Matsushima, Takatsugu Ono, Masaaki Murata, Yoshikazu Miyazawa, Yoshinori Okuno, Kazutoshi Ishikawa, Toshiharu Inagaki, Hirokimi Shinguu, and Tadao Uchida Jul. 1992 70 p In JAPANESE

(NAL-TR-1175; JTN-93-80491) Avail: CASI HC A04/MF A01

Flight experiments conducted at the Sendai airport (under a joint research project with National Aerospace Laboratory (NAL), National Space Development Agency (NASDA), and Electronic Navigation Research Institute (ENRI) in partial co-operation with Toshiba and NEC Corporations) were utilized to evaluate and establish new navigation sensor technologies which will play a key role in the unmanned spaceplane HOPE (H-2 Orbiting Plane) approach/landing (A/L) navigation system design. The Dornier-228-200 (Do-228), an experimental research aircraft of NAL, is used for the flight experiments. The navigation sensors tested include the Microwave Landing System (MLS), Global Positioning System (GPS), Inertial Navigation System (INS), and radio altimeter. The Differential GPS (DGPS) was also tested in both stand-alone and hybrid modes. The Do-228 is tracked during flight by a laser tracker, with subsequent data being used to provide a reference profile of the aircraft. Navigation accuracy is evaluated in the post-flight performance analysis as the difference between reference profile and navigation output from each navigation sensor or hybrid system. This comparison is made in the Runway Coordinate System (RCS), a reference navigation coordinate system which corresponds to the World Geodetic System 1984 (WGS84). The RCS was constructed using GPS interferometric positioning. In this report, emphasis is placed on describing the tested navigation sensors, data acquisition systems, ground guidance facilities, flight patterns, and analysis strategies. Some preliminary analysis results are also presented which evaluate the stand-alone performance of each navigation sensor as well as a hybrid GPS-INS system.

PERFORMANCE EVALUATION TESTS OF THE GPS/DGPS NAVIGATION SYSTEM INSTALLED IN THE NAL DORNIER 228: PRELIMINARY GROUND TEST RESULTS [JIKKENYOU KOUKUUKI DORUNIEKI NO GPS KOUHOU SOUCHI HYOUKA JIKKEN: CHIJOU KOTEITEN NIOKERU GPS/DGPS SOUKUI HYOUKA JIKKEN]

Takatsugu Ono and Kazutoshi Ishikawa Aug. 1992 19 p In JAPANESE

(NAL-TM-649; JTN-93-80493) Avail: CASI HC A03/MF A01

A real-time Differential Global Positioning System (DGPS), incorporating a ground-to-air data link system, was developed for the National Aerospace Laboratory (NAL) Dornier 228-200 flight research airplane. Preliminary ground tests were conducted to evaluate the system's position accuracy prior to flight testing. The onboard and ground GPS receivers used the same antenna in order to avoid unknown common errors (e.g., antenna system and tropospheric delays), and to enable comparison of the optimal case of differential operation. The GPS position accuracies of the stand-alone and differential modes are compared, with results showing that the differential mode improves position accuracy and eliminates Selective Availability (SA) errors. FLIGHT PATH CONTROL FOR THE APPROACH AND LANDING OF THE QUIET STOL EXPERIMENTAL AIRCRAFT ASKA [TEISOUON STOL JIKKENKI ASKA NO KEIROKAKU SEIGYO TO CHAKURIKU SOUJUUSEI]

Noriaki Okada Nov. 1992 53 p In JAPANESE

(NAL-TR-1183; JTN-93-80505) Avail: CASI HC A04/MF A01

The Upper Surface Blowing STOL experimental aircraft, ASKA, operates well on the backside of the power required curve, so flight path control is accomplished with the throttle lever (thrust) during landing approaches. To compensate for the sluggish flight path response caused by engine lag, the Flight Path Control (FPC) law engages the Stability and Control Augmentation System (SCAS). Flight tests were conducted to evaluate flight path and airspeed response characteristics. This paper describes ASKA's flight path and airspeed response characteristics, as well as the principle involved in the design and construction of the FPC system.

GPS SATELLITE SKY DISTRIBUTION: IMPACT ON THE PROPAGATION OF SOME IMPORTANT ERRORS IN PRECISE RELATIVE POSITIONING Ph.D. Thesis

Rock Santerre Sep. 1989 221 p

(ISBN-0-315-51838-3; CTN-93-60726) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

The impact of the Global Positioning System (GPS) satellite sky distribution on the propagation of some important errors in precise static relative positioning is investigated, for baselines shorter than about 100 km. The study uses an improved and expanded simulation technique in which the unknowns are the station coordinates, the relative receiver clock parameter, and the relative tropospheric zenith delay parameter. Biases analyzed are the relative tropospheric refraction, absolute ionospheric refraction, offset in horizontal coordinates of the fixed station, and offset in the height of the fixed station. The simulation results agree with those obtained from real GPS data processing with an associated error of about 25%. Orientation and shape of the confidence ellipsoid, and correlation among the selected unknowns, are used to monitor the behavior of the covariance matrix. Systematic errors introduced in the station network by the biases are represented as station coordinate discrepancies and affine transformation parameters. Numerical values of these parameters are presented for satellite configurations produced by both the prototype and the full GPS constellations. The magnitudes of the effects of the studied biases are up to 10 cm for baseline length independent errors and up to 10 ppM for baseline length dependent errors. Author (CISTI)

EVALUATION OF INFRARED SENSORS FOR AUTONOMOUS LANDING GUIDANCE Final Report, 1 May - 30 Jun. 1992

Anthony E. Absi Apr. 1993 25 p

(AD-A266450; WL-TR-93-1054) Avail: CASI HC A03/MF A01

The objective of this program is to test sensors that could provide pilots with images of runway and landing zones under degraded weather conditions such as rain, snow, and fog. During these conditions pilots are unable to land aircraft by visual reference alone. Imaging RF and EO sensors may be able to provide a view of the runway or landing zone that is unaffected by degraded weather. Autonomous landing systems would allow operations at airfields not served by conventional ground-based radio landing aids and allow military operations at unprepared landing sites or drop zones. A test was conducted at Otis Air National Guard Base by Wright Laboratory personnel in June 1992 during heavy fog. Typical staring midwave infrared sensors were used to image a simulated runway (1500 foot asphalt pad) and grass background. The distance at which the pad could no longer be discerned was measured along with supporting meteorological and radiometric ground truth data. This report presents the results and compares them to standard infrared sensor performance prediction models. DTIC

OBSTACLE DETECTION BY RECOGNIZING BINARY EXPANSION PATTERNS Annual Progress Report
Yoram Baram (Israel Inst. of Tech., Haifa.) and Yair Barniv (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.) 20 Sep. 1993 15 p
(Contract NCC2-703)
(NASA-CR-194415; NAS 1.26:194415) Avail: CASI HC A03/MF A01

This paper describes a technique for obstacle detection, based on the expansion of the image-plane projection of a textured object, as its distance from the sensor decreases. Information is conveyed by vectors whose components represent first-order temporal and spatial derivatives of the image intensity, which are related to the time to collision through the local divergence. Such vectors may be characterized as patterns corresponding to 'safe' or 'dangerous' situations. We show that essential information is conveyed by single-bit vector components, representing the signs of the relevant derivatives. We use two recently developed, high capacity classifiers, employing neural learning techniques, to recognize the imminence of collision from such patterns. Author (revised)

DETERMINATION OF LORAN-C/GPS HUMAN FACTORS ISSUES Final Report, Aug. 1992 - Mar. 1993
R. J. Adams, C. A. Adams, D. Eldredge, and M. S. Huntley Apr. 1993 38 p Prepared in cooperation with Advanced Aviation Concepts, Jupiter, FL Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-199693; DOT-VNTSC-FAA-93-3; DOT/FAA/RD-93/4) Avail: CASI HC A03

The report identifies human factors issues and the problems that general aviation pilots have using Loran-C navigation systems in the National Airspace System (NAS). The issues discussed include system design, software logic, and handbook and training problems. Data was collected from group discussions with active pilots throughout the eastern United States and Canada during late 1991 and the first half of 1992. These discussions included air carrier, air taxi, corporate, business, and pleasure users of Loran-C and a limited number of GPS users. The purpose of the study was to anticipate the potential human factor problems that could be expected in the full integration of GPS into the NAS. NTIS

A METHOD OF PREDICTING QUASI-STEADY AERODYNAMICS FOR FLUTTER ANALYSIS OF HIGH SPEED VEHICLES USING STEADY CFD CALCULATIONS
Robert C. Scott and Anthony S. Pototzky (Lockheed Engineering and Sciences Co., Hampton, VA.) Jul. 1993 10 p Presented at the AIAA 34th Structures, Structural Dynamics, and Materials Conference, LaJolla, CA, 19-21 Apr. 1993 Previously announced in IAA as A93-33931
(RTOP 505-63-50-15)
(NASA-TM-109009; NAS 1.15:109009) Avail: CASI HC A02/MF A01

High speed linear aerodynamic theories like piston theory and Newtonian impact theory are relatively inexpensive to use for flutter analysis. These theories have limited areas of applicability depending on the configuration and the flow conditions. In addition, these theories lack the ability to capture viscous, shock, and real gas effects. CFD methods can model all of these effects accurately, but the unsteady calculations required for flutter are expensive and often impractical. This paper describes a method for using steady CFD calculations to approximate the generalized aerodynamic forces for a flutter analysis. Example two-and three-dimensional aerodynamic force calculations are provided. In addition, a flutter analysis of a NASP-type wing will be discussed. Author (revised)

DEVELOPMENT OF AN ON-BOARD AIRCRAFT OPTICAL FIBER DATA BUS SYSTEM [KOUKUUKI TOUSAIGATA HIKARI DETABASU NO KAIHATSU]
Mitsuyoshi Mayanagi, Minoru Takizawa, Tadao Uchida, Toshiharu Inagaki, Kouki Hozumi, and Kazutoshi Ishikawa Jun. 1992 87 p In JAPANESE
(NAL-TR-1163; JTN-93-80485) Avail: CASI HC A05/MF A01

An optical fiber data bus system was developed to provide the necessary technological foundation to use on a Fly-By-Light (FBL) control system which will be required on future aircraft. This data bus system was designed and built in accordance with the protocol and system organization requirements set forth in MIL-STD-1553B (USAF). It is an on-board model comprised of a bus control unit, two remote terminal units, an optical transmission unit having three optical transmitters/receivers. an eight to eight star coupler, a pressurized bulkhead optical connector, and three sets of fiber optic cables. A single fiber optic cable is utilized as the data transmission medium, and it employs a newly developed electrically passive/transmitting eight to eight star coupler and a pressurized bulkhead optical connector for optical coupling. New serial bus control and message handling techniques were also developed for the data bus. In addition, an electrical transmission line is provided to back up the optical fiber transmission line, thereby, providing the necessary system reliability for testing the FBL control system. Performance evaluations of the optical fiber data bus were conducted by testing the optical transmission units, and by conducting environmental, laboratory, and flight test with results verifying suitable adaptability to the FBL control system. HYPERSONIC AERODYNAMIC CHARACTERISTICS OF SSTO-TYPE AEROSPACE PLANES. PART 1: THE NAL 0-th CONFIGURATION [SUPESUPUREN NO GOKUCHOUONSOKU KUURIKI TOKUSEI SHIKEN: DAI 0-JI KEIJOU]
Shigeya Watanabe, Kouichi Hozumi, Akira Yoshizawa, Tadao Koyama, and Shouichi Tsuda Dec. 1992 57 p In JAPANESE
(NAL-TR-1186; JTN-93-80507) Avail: CASI HC A04/MF A01

Tests to determine the aerodynamic characteristics of a horizontal takeoff, Single Stage To Orbit (SSTO) type aerospace plane (NAL 0-th configuration) were conducted at a Mach number of 7.1. Six components of force and

moment were measured in the blowdown-type 50 cm hypersonic wind tunnel at the National Aerospace Laboratory. Flow visualizations were also performed using the schlieren, surface oil flow, and vapor screen techniques. The force and moment test results showed that the configuration had a lift-to-drag ratio of 2.2 in the ascent flight condition and that Dutch-roll mode instability occurred due to directional instability. The focus of future aerodynamic configuration improvements are discussed in connection with these results. Author (NASDA)

MULTIDISCIPLINARY DESIGN TECHNIQUES APPLIED TO CONCEPTUAL AEROSPACE VEHICLE DESIGN Ph.D. Thesis Final Technical Report

John Robert Olds and Gerald D. Walberg 1993 181 p
(Contract NCC1-168)
(NASA-CR-194409; NAS 1.26:194409) Avail: CASI HC A09/MF A02

Multidisciplinary design optimization (MDO) is an emerging discipline within aerospace engineering. Its goal is to bring structure and efficiency to the complex design process associated with advanced aerospace launch vehicles. Aerospace vehicles generally require input from a variety of traditional aerospace disciplines - aerodynamics, structures, performance, etc. As such, traditional optimization methods cannot always be applied. Several multidisciplinary techniques and methods were proposed as potentially applicable to this class of design problem. Among the candidate options are calculus-based (or gradient-based) optimization schemes and parametric schemes based on design of experiments theory. A brief overview of several applicable multidisciplinary design optimization methods is included. Methods from the calculus-based class and the parametric class are reviewed, but the research application reported focuses on methods from the parametric class. A vehicle of current interest was chosen as a test application for this research. The rocket-based combined-cycle (RBCC) single-stage-to-orbit (SSTO) launch vehicle combines elements of rocket and airbreathing propulsion in an attempt to produce an attractive option for launching medium sized payloads into low earth orbit. The RBCC SSTO presents a particularly difficult problem for traditional one-variable-at-a-time optimization methods because of the lack of an adequate experience base and the highly coupled nature of the design variables. MDO, however, with it's structured approach to design, is well suited to this problem. The result of the application of Taguchi methods, central composite designs, and response surface methods to the design optimization of the RBCC SSTO are presented. Attention is given to the aspect of Taguchi methods that attempts to locate a 'robust' design - that is, a design that is least sensitive to uncontrollable influences on the design. Near-optimum minimum dry weight solutions are determined for the vehicle. A summary and evaluation of the various parametric MDO methods employed in the research are included. Recommendations for additional research are provided. Author (revised)

DEVELOPMENT AND APPLICATION OF A COMPREHENSIVE, DESIGN-SENSITIVE WEIGHT PREDICTION METHOD FOR WING STRUCTURES OF TRANSPORT CATEGORY AIRCRAFT

E. Torenbeek Sep. 1992 59 p
(LR-693; ETN-93-94417) Avail: CASI HC A04/MF A01

The development of an analytical empirical method to predict the structural weight of transport aircraft wings is described. The method is suitable for the preliminary design stage, when sensitivity studies are required of the effects of geometry and other variations on the design characteristics. The wing weight is computed as the sum of several functional components. The basic weight required to resist bending and shear loads is computed from integration of a spanwise material distribution. Weight penalties are derived for nonoptimum effects, including stiffness required to cope with aeroelastic effects. Methods for leading and trailing edge structures, including high lift devices and control surfaces are derived. Instead of using the suggested statistical data for mean stress levels, the user may input more accurate data, if available. The baseline is 1980+ technology. The method is applied to present day transport aircraft. For the cases considered the prediction error was below 4%. ESA

COMPUTATIONAL METHODS FOR RELIABLE FATIGUE AND DAMAGE TOLERANCE DIMENSIONING OF AIRCRAFT STRUCTURES

Boerje Andersson Feb. 1993 23 p Presented at the 5th Nordic Seminar on Computational Mechanics, Aalborg, Denmark, 5-6 Nov. 1992 Sponsored by Defence Material Administration, Stockholm, Sweden
(FFA-TN-1993-05; ETN-93-94489) Avail: CASI HC A03/MF A01

A computational procedure for reliable stress and linear elastic fracture mechanics analysis of aircraft components of high complexity is described. The numerical analysis is based on the h-p version of the finite element method. For analysis of stresses at fillets, a rational analysis procedure is developed. From one three dimensional fracture mechanics analysis, analytical formulae are obtained that accurately predict pointwise stresses as a function of geometry parameters, for example, the radius at a fillet. A model example is analyzed in order to demonstrate the simplicity, reliability, and accuracy obtainable with the suggested approach. Results from an analysis of an aircraft fuselage, using a model having two million degrees of freedom, exemplify the practical usefulness of the procedure when solving very complex aircraft design problems. ESA

AN ANALYSIS OF HELICOPTER ATTRITION USING A LOW LEVEL COMBAT SIMULATION

P. J. Young and R. J. Hill Dec. 1992 66 p
(DSIS-93-00282; DLOR-RN-92-5; CTN-93-60797) Avail: CASI HC A04/MF A01

Low level combat simulations were applied to study the attrition of utility tactical transport helicopters (UTTH's) in their proposed roles as the Canadian Army's sole tactical aviation asset. A preliminary analysis is presented of the UTTH in the reconnaissance role only, using the HELSCAM combat simulator program. The effects of the flown nap-of-the-earth altitude and the physical signature of a reconnaissance helicopter on its survivability are examined. The scenarios were simulated with the UTTH at two altitudes: 2 m and 5 m. The observed loss rate at the higher altitude was more than double that at the lower altitude. In addition, the larger size of the UTTH compared to a conventional light observation helicopter operating at the same altitude, increased its loss rate by about 18 percent. The results suggest that the operational doctrine used for the UTTH can have a significant impact on its potential survivability and hence on its performance. Author (CISTI)

HELSCAM V2.0: DEVELOPMENT AND APPLICATION GUIDE

P. J. Young Dec. 1992 128 p
(DSIS-93-00137; DLOR-RN-92-6; CTN-93-60805) Avail: CASI HC A07

The HELicopter SCenario Assessment Model (HELSCAM) was developed to study helicopter operations in support of the ground commander. The completed model comprised a simulation core, an event analyzer, and graphical facilities for route planning and scenario replay. The simulation core included sophisticated algorithms for movement, acquisition, and engagement processes. In the process of streamlining the model and generalizing its algorithms to model a wider variety of weapon systems, HELSCAM changed sufficiently to require a new development and application guide, which is presented. Major modifications to the simulation core of HELSCAM present in the new version 2.0 include addition of fixed wing systems, addition of a merged terrain base in the terrain data files, the modelling of delays imposed by weapon reloading, and revision of the line-of-sight algorithm. The guide includes an overview of HELSCAM system

hardware and software requirements, the simulation core, the analytical facility, and input definitions. An air raid scenario and its HELSCAM files are also included. CISTI

QUALITATIVE INVESTIGATION OF A GENERIC FIGHTER MODEL IN RADIO CONTROLLED GLIDING FLIGHT
P. J. Penna Jul. 1992 26 p
(LM-AA-003; CTN-93-60762) Avail: CASI HC A03/MF A01

A generic fighter model was flown in radio controlled gliding flight to investigate qualitatively some of its flight dynamic characteristics. Visual cues from the model's flight path, its motion about its center of gravity, and qualitative knowledge of the pilot's control inputs were used to infer certain dynamic characteristics. The observations showed that the model was statically stable in pitch with the center of gravity moved as far back as 23.3 percent of the mean aerodynamic chord of the wing. However, if the model was rotated rapidly in pitch, it had a tendency to pitch up into a deep stall. The model was found to be prone to entering a spin from a moderate stall. The spin is postulated to be caused by a separated-flow asymmetry at the nose ogive. Finally, the model's ailerons were found to provide acceptable roll control authority, but maximum aileron deflection caused visible adverse yaw. CISTI

FLIGHT VALIDATION OF A PULSED SMOKE FLOW VISUALIZATION SYSTEM Final Report
Donald T. Ward and Kenneth M. Dorsett Sep. 1993 44 p Sponsored by NASA. Washington
(Contract NCC2-742; RTOP 533-02-35)
(NASA-CR-186026; H-1914; NAS 1.26:186026) Avail: CASI HC A03/MF A01

A flow visualization scheme, designed to measure vortex fluid dynamics on research aircraft, was validated in flight. Strake vortex trajectories and axial core velocities were determined using pulsed smoke, high-speed video images, and semiautomated image edge detection hardware and software. Smoke was pulsed by using a fast-acting three-way valve. After being redesigned because of repeatedly jamming in flight, the valve shuttle operated flawlessly during the last two tests. A 25-percent scale, Gothic strake was used to generate vortex over the wing of a GA-7 Cougar and was operated at a local angle of attack of 22 degrees and Reynolds number of approximately 7.8 x 10(exp 5)/ft. Maximum axial velocities measured in the vortex core were between 1.75 and 1.95 times the freestream velocity. Analysis of the pulsed smoke system's affect on forebody vortices indicates that the system may reorient the forebody vortex system; however, blowing momentum coefficients normally used will have no appreciable affect on the leading-edge extension vortex system. It is recommended that a similar pulsed smoke system be installed on the F/A-18 High Angle Research Vehicle and that this approach be used to analyze vortex core dynamics during the remainder of its high-angle-of-attack research flights. FLIGHT CREW INTERFACE ASPECTS OF FORWARD-LOOKING AIRBORNE WINDSHEAR DETECTION SYSTEMS Final Report
Charles D. Anderson and David C. Carbaugh Jul. 1993 124 p Original contains color illustrations
(Contract NAS1-18027; RTOP 505-64-12-01)
(NASA-CR-191437; NAS 1.26:191437) Avail: CASI HC A06/MF A02; 11 functional color pages

The goal of this research effort was to conduct analyses and research which could provide guidelines for design of the crew interface of an integrated windshear system. Addressed were HF issues, crew/system requirements, candidate display formats, alerting criteria, and crew procedures. A survey identified five flight management issues as top priority: missed alert acceptability; avoidance distance needed; false alert acceptability; nuisance rate acceptability; and crew procedures. Results of a simulation study indicated that the warning time for a look-ahead alert needs to be between 11 and 36 seconds (target of 23 seconds) before the reactive system triggers in order to be effective. Pilots considered the standard go-around maneuver most appropriate for look-ahead alerts, and the escape maneuvers used did not require lateral turns. Prototype display formats were reviewed or developed for alerting the crew; providing guidance to avoid or escape windshear; and status displays to provide windshear situational awareness. The three alerting levels now in use were considered appropriate, with a fourth (time-critical) level as a possible addition, although many reviewers felt only two levels of alerting were needed. Another survey gathered expert opinion on what crew procedures and alerting criteria should be used for look-ahead, or integrated, windshear systems, with a wide diversity of opinion in these areas. A review of the requirement for, and development of, advanced measurement technology for the National Aerospace Plane program is

presented. The objective is to discuss the technical need and the program commitment required to ensure that adequate and timely measurement capabilities are provided for ground and flight testing in the NASP program. The scope of the measurement problem is presented, the measurement process is described, how instrumentation technology development has been affected by NASP program evolution is examined, the national effort to define measurement requirements and assess the adequacy of current technology to support the NASP program is discussed, and the measurement requirements are summarized. The unique features of the NASP program that complicate the understanding of requirements and the development of viable solutions are illustrated. Author (revised)

POSITION ERROR DETERMINATION FOR THE SPEEDOMETER AND ALTIMETER OF THE NAL QSTOL EXPERIMENTAL AIRCRAFT ASKA [TEISOUON SHORT TAKE-OFF AND LANDING JIKKENKI ASUKA NO SOKUDOKEI OYOBI KOUDOKEI NO ICHI GOSA]

Kazuya Masui, Hamaki Inokuchi, and Kenji Yazawa Mar. 1992 69 p In JAPANESE

(NAL-TR-1144; JTN-93-80482) Avail: CASI HC A04/MF A01

The position error is reported for three different pitot-static systems used in the National Aerospace Laboratory (NAL) Quiet Short Take-Off and Landing (QSTOL) experimental aircraft, ASKA, being determined using only the static pressure error, and assuming that the total pressure error is negligible. It was found that a continuous reference altitude and a correction for pressure propagation lag, realized the determination of the position error during speed and altitude transition. The continuous reference altitude was obtained precisely by the combination of a radar altimeter and an aircraft tracking radar. The ground effect on the position error before touchdown is also reported. In addition, the position error in high angle of attack cases was discussed. The resultant position error correction was used for various analyses of flight test data. Furthermore, it was incorporated into the Digital Air Data Computer to indicate the calibrated airspeed and altitude to the pilots. Author (NASDA)

FUNCTIONAL CATEGORIES FOR FUTURE FLIGHT DECK DESIGNS

Terence S. Abbott Aug. 1993 15 p

(RTOP 505-64-53-02)

(NASA-TM-109005; NAS 1.15:109005) Avail: CASI HC A03/MF A01

With the addition of each new system on the flight deck, the danger of increasing overall operator workload while reducing crew understanding of critical mission information exists. The introduction of more powerful onboard computers, larger databases, and the increased use of electronic display media may lead to a situation of flight deck 'sophistication' at the expense of losses in flight crew capabilities and situational awareness. To counter this potentially negative impact of new technology, research activities are underway to reassess the flight deck design process. The fundamental premise of these activities is that a human-centered, systems-oriented approach to the development of advanced civil aircraft flight decks will be required for future designs to remain ergonomically sound and economically competitive. One of the initial steps in an integrated flight deck process is to define the primary flight deck functions needed to support the mission goals of the vehicle. This would allow the design team to evaluate candidate concepts in relation to their effectiveness in meeting the functional requirements. In addition, this would provide a framework to aid in categorizing and bookkeeping all of the activities that are required to be performed on the flight deck, not just activities of the crew or of a specific system. This could then allow for a better understanding and allocation of activities in the design, an understanding of the impact of a specific system on overall system performance, and an awareness of the total crew performance requirements for the design. One candidate set of functional categories that could be used to guide an advanced flight deck design are described. Author (revised)

RECENT FLIGHT-TEST RESULTS OF OPTICAL AIRDATA TECHNIQUES

Rodney K. Bogue Washington May 1993 22 p Presented at the SAE Aerotech 1992, Anaheim, CA, 5-8 Oct. 1992

(RTOP 505-68-50)

(NASA-TM-4504; H-1915; NAS 1.15:4504; SAE-92-1997) Avail: CASI HC A03/MF A01

Optical techniques for measuring airdata parameters were demonstrated with promising results on high performance fighter aircraft. These systems can measure the airspeed vector, and some are not as dependent on special in-flight calibration processes as current systems. Optical concepts for measuring freestream static temperature and density are feasible for in-flight applications. The best feature of these concepts is that the air data measurements are obtained nonintrusively, and for the most part well into the freestream region of the flow field about the aircraft. Current requirements for measuring air data at high angle of attack, and future need to measure the same information at hypersonic flight conditions place strains on existing techniques. Optical technology advances show outstanding potential for application in future programs and promise to make common use of optical concepts a reality. Results from several flight-test programs are summarized, and the technology advances required to make optical airdata techniques practical are identified.

COMBUSTOR TECHNOLOGY FOR FUTURE SMALL GAS TURBINE AIRCRAFT

Valerie J. Lyons and Richard W. Niedzwiecki Aug. 1993 18 p Proposed for presentation at the Propulsion and Energetics Panel 82nd Meeting, Montreal, Ottawa, 4-8 Oct. 1993; sponsored by the Advisory Group for Aerospace Research and Development

(RTOP 535-05-10)

(NASA-TM-106312; E-8052; NAS 1.15:106312) Avail: CASI HC A03/MF A01

Future engine cycles proposed for advanced small gas turbine engines will increase the severity of the operating conditions of the combustor. These cycles call for increased overall engine pressure ratios which increase combustor inlet pressure and temperature. Further, the temperature rise through the combustor and the corresponding exit temperature also increase. Future combustor technology needs for small gas turbine engines is described. New fuel injectors with large turndown ratios which produce uniform circumferential and radial temperature patterns will be required. Uniform burning will be of greater importance because hot gas temperatures will approach turbine material limits. The higher combustion temperatures and increased radiation at high pressures will put a greater heat load on the combustor liners. At the same time, less cooling air will be available as more of the air will be used for combustion. Thus, improved cooling concepts and/or materials requiring little or no direct cooling will be required.

Although presently there are no requirements for emissions levels from small gas turbine engines, regulation is expected in the near future. This will require the development of low emission combustors. In particular, nitrogen oxides will increase substantially if new technologies limiting their formation are not evolved and implemented. For example, staged combustion employing lean, premixed/prevaporized, lean direct injection, or rich burn-quick quench-lean burn concepts could replace conventional single stage combustors. Author

ANALYSIS OF GAS TURBINE ENGINES USING WATER AND OXYGEN INJECTION TO ACHIEVE HIGH MACH NUMBERS AND HIGH THRUST

Hugh M. Henneberry (Analex Corp., Brook Park, OH.) and Christopher A. Snyder Jul. 1993 20 p

(RTOP 505-70-00)

(NASA-TM-106270; E-7998; NAS 1.15:106270) Avail: CASI HC A03/MF A01

An analysis of gas turbine engines using water and oxygen injection to enhance performance by increasing Mach number capability and by increasing thrust is described. The liquids are injected, either separately or together, into the subsonic diffuser ahead of the engine compressor. A turbojet engine and a mixed-flow turbofan engine (MFTF) are examined, and in pursuit of maximum thrust, both engines are fitted with afterburners. The results indicate that water injection alone can extend the performance envelope of both engine types by one and one-half Mach numbers at which point water-air ratios reach 17 or 18 percent and liquid specific impulse is reduced to some 390 to 470 seconds, a level about equal to the impulse of a high energy rocket engine. The envelope can be further extended, but only with increasing sacrifices in liquid specific impulse. Oxygen-airflow ratios as high as 15 percent were investigated for increasing thrust. Using 15 percent oxygen in combination with water injection at high supersonic Mach numbers resulted in thrust augmentation as high as 76 percent without any significant decrease in liquid specific impulse. The stoichiometric afterburner exit temperature increased with increasing oxygen flow, reaching 4822 deg R in the turbojet engine at a Mach number of 3.5. At the transonic Mach number of 0.95 where no water injection is needed, an oxygen-air ratio of 15 percent increased thrust by some 55 percent in both engines, along with a decrease in liquid specific impulse of 62 percent. Afterburner temperature was approximately 4700 deg R at this high thrust condition. Water and/or oxygen injection are simple and straightforward strategies to improve engine performance and they will add little to engine weight. However, if large Mach number and thrust increases are required, liquid flows become significant, so that operation at these conditions will necessarily be of short duration. Author (revised)

AN EXPERIMENTAL INVESTIGATION OF MIXING ENHANCEMENT IN A SIMULATED SCRAMJET COMBUSTOR BY USE OF SWIRLING JETS

M.S. Thesis

Donna Karen Kraus Aug. 1993 92 p Original contains color illustrations

(NASA-TM-109246; NAS 1.15:109246) Avail: CASI HC A05/MF A01; 4 functional color pages

It is desired to maintain supersonic flow through the combustor of supersonic airbreathing engines to reduce static temperatures and total pressure losses inherent in reducing flow to subsonic speeds. Due to the supersonic speeds through the combustor, mixing of the fuel and air must by rapid for complete combustion to occur within a reasonable streamwise distance. It was proposed that the addition of swirl to the fuel jet prior to injection might enhance the mixing of the fuel with the air. The effects of swirl on the mixing of a 30 deg wall jet into a Mach 2 flow were experimentally investigated. Swirl was introduced into the fuel stream by tangential injection into a cylindrical swirl chamber. The flow was then accelerated through a convergent-divergent nozzle with an area ratio of two, and supersonically injected into the Mach 2 flow such that the static pressure of the fuel matched the effective back pressure of the main flow. Two different cases with swirl and one without swirl were investigated, with both helium and air simulating the fuel. Rayleigh scattering was used to visualize the flow and seeding the fuel with water allowed it to be traced through the main flow. Using histograms of the pure molecular Rayleigh scattering images, the helium concentration in the jet-mixing region of the flow was monitored and found to decrease slightly with swirl, indicating better mixing. Thresholding the water-seeded images allowed the jet-mixing region to be isolated and showed a slight increase in this area with swirl. Penetration, however, was slightly less with swirl. Rescaling the data for equal mass flow rates allowed comparison for a scramjet application of a combustor with a single injector and the desire to fuel to a specified fuel-to-oxidant ratio. These results showed a substantial increase in the spreading area with swirl, an increase in the mixing occurring in this area, and slightly better penetration. Author (revised)

AIRCRAFT ENGINE TYPE CERTIFICATION HANDBOOK: ADVISORY CIRCULAR

30 Jun. 1993 125 p Supersedes AC-33-2A

(AC-33-2B; ANE-110) Avail: CASI HC A06/MF A02

This advisory circular (AC) provides methods acceptable to the Administrator for showing compliance with the type certification requirements of aircraft engines in Part 33, inclusive through amendment 12, of the Federal Aviation Regulations (FAR). The procedures and guidance material provided in this AC may be used by an applicant seeking issuance of a type certificate, an amended type certificate, or a supplemental type certificate for the initial approval of a new type design, or a change in the type design. Consideration will be given to any other method of compliance the applicant elects to present. This information is not in itself mandatory, but serves as a guide to engine manufacturers, engine modifiers, and Federal Aviation Administration (FAA) engine type certification engineers. Individuals should be guided by the intent of the methods provided in this AC. Author

NOISE LEVELS FROM A MODEL TURBOFAN ENGINE WITH SIMULATED NOISE CONTROL MEASURES APPLIED

David G. Hall (Sverdrup Technology, Inc., Brook Park, OH.) and Richard P. Woodward Oct. 1993 15 p Proposed for presentation at the 15th AIAA Aeroacoustics Conference, Long Beach, CA, 25-27 Oct. 1993; sponsored by AIAA

(RTOP 535-03-10)

(NASA-TM-106318; E-8063; NAS 1.15:106318; AIAA Paper 93-4401)

Avail: CASI HC A03/MF A01

A study of estimated full-scale noise levels based on measured levels from the Advanced Ducted Propeller (ADP) sub-scale model is presented. Testing of this model was performed in the NASA Lewis Low Speed Anechoic Wind Tunnel at a simulated takeoff condition of Mach 0.2. Effective Perceived Noise Level (EPNL) estimates for the baseline configuration are documented, and also used as the control case in a study of the potential benefits of two categories of noise control. The effect of active noise control is evaluated by artificially removing various rotor-stator interaction tones. Passive noise control is simulated by applying a notch filter to the wind tunnel data. Cases with both techniques are included to evaluate

hybrid active-passive noise control. The results for EPNL values are approximate because the original source data was limited in bandwidth and in sideline angular coverage. The main emphasis is on comparisons between the baseline and configurations with simulated noise control measures. Author (revised)

THREE-DIMENSIONAL MODELING OF DIESEL ENGINE INTAKE FLOW, COMBUSTION AND EMISSIONS-2 Final Report
R. D. Reitz and C. J. Rutland Sep. 1993 64 p
(Contract NAG3-1087; DE-AI01-91CE-50306; RTOP 778-34-2A)
(NASA-CR-191189; E-8103; NAS 1.26:191189; DOE/NASA/1087-2)
Avail: CASI HC A04/MF A01

A three-dimensional computer code, KIVA, is being modified to include state-of-the-art submodels for diesel engine flow and combustion. Improved and/or new submodels which have already been implemented and previously reported are: wall heat transfer with unsteadiness and compressibility, laminar-turbulent characteristic time combustion with unburned HC and Zeldo'vich NO(x), and spray/wall impingement with rebounding and sliding drops. Progress on the implementation of improved spray drop drag and drop breakup models, the formulation and testing of a multistep kinetics ignition model, and preliminary soot modeling results are described. In addition, the use of a block structured version of KIVA to model the intake flow process is described. A grid generation scheme was developed for modeling realistic (complex) engine geometries, and computations were made of intake flow in the ports and combustion chamber of a two-intake-value engine. The research also involves the use of the code to assess the effects of subprocesses on diesel engine performance. The accuracy of the predictions is being tested by comparisons with engine experiments. To date, comparisons were made with measured engine cylinder pressure, temperature and heat flux data, and the model results are in good agreement with the experiments. Work is in progress that will allow validation of in-cylinder flow and soot formation predictions. An engine test facility is described that is being used to provide the needed validation data. Test results were obtained showing the effect of injection rate and split injections on engine performance and emissions. Author (revised)

PERFORMANCE OF GAS TURBINE COMPRESSOR CLEANERS [WASMIDDELEN VOOR GASTURBINES VALLEN VIES TEGEN]
H. J. Kolkman 23 Jul. 1991 15 p In DUTCH Submitted for publication
(NLR-TP-91291-U; ETN-93-94068) Avail: CASI HC A03/MF A01

The cleaning efficiency of compressor cleaners was studied. Recently developed cleaners are claimed to be ecologically sound. In addition, many new compressor cleaners contain a corrosion inhibitor. The cleaning efficiency of eight (old and new) compressor cleaners was determined by simulated compressor washing of compressor blades that had become foul in service. For the situation simulated, the cleaning efficiency of new, ecologically sound cleaners turned out to be poor as compared with old cleaners. ESA

An improved methodology for quantitatively evaluating failure risk of spaceflight systems to assess flight readiness and identify risk control measures is presented. This methodology, called Probabilistic Failure Assessment (PFA), combines operating experience from tests and flights with analytical modeling of failure phenomena to estimate failure risk. The PFA methodology is of particular value when information on which to base an assessment of failure risk, including test experience and knowledge of parameters used in analytical modeling, is expensive or difficult to acquire. The PFA methodology is a prescribed statistical structure in which analytical models that characterize failure phenomena are used conjointly with uncertainties about analysis parameters and/or modeling accuracy to estimate failure probability distributions for specific failure modes. These distributions can then be modified, by means of statistical procedures of the PFA methodology, to reflect any test or flight experience. State-of-the-art analytical models currently employed for designs failure prediction, or performance analysis are used in this methodology. The rationale for the statistical approach taken in the PFA methodology is discussed, the PFA methodology is described, and examples of its application to structural failure modes are presented. The engineering models and computer software used in fatigue crack growth and fatigue crack initiation applications are thoroughly documented. Author (revised)

A flight test evaluation of the performance-seeking control (PSC) algorithm on the NASA F-15 highly integrated digital electronic control research aircraft was conducted for single-engine operation at subsonic and supersonic speeds. The model-based PSC system was developed with three optimization modes: minimum fuel flow at constant thrust, minimum turbine temperature at constant thrust, and maximum thrust at maximum dry and full afterburner throttle settings. Subsonic and supersonic flight testing were conducted at the NASA Dryden Flight Research Facility covering the three PSC optimization modes and over the full throttle range. Flight results show substantial benefits. In the maximum thrust mode, thrust increased up to 15 percent at subsonic and 10 percent at supersonic flight conditions. The minimum fan turbine inlet temperature mode reduced temperatures by more than 100 F at high altitudes. The minimum fuel flow mode results decreased fuel consumption up to 2 percent in the subsonic regime and almost 10 percent supersonically. These results demonstrate that PSC technology can benefit the next generation of fighter or transport aircraft. NASA Dryden is developing an adaptive aircraft performance technology system that is measurement based and uses feedback to ensure

optimality. This program will address the technical weaknesses identified in the PSC program and will increase performance gains. Author (revised)

TURBULENCE MODELING OF FREE SHEAR LAYERS FOR HIGH-PERFORMANCE AIRCRAFT Progress Report
Douglas L. Sondak Aug. 1993 9 p
(Contract NCC2-663)
(NASA-CR-193659; NAS 1.26:193659; MCAT-93-15) Avail: CASI HC A02/MF A01

The High Performance Aircraft (HPA) Grand Challenge of the High Performance Computing and Communications (HPCC) program involves the computation of the flow over a high performance aircraft. A variety of free shear layers, including mixing layers over cavities, impinging jets, blown flaps, and exhaust plumes, may be encountered in such flowfields. Since these free shear layers are usually turbulent, appropriate turbulence models must be utilized in computations in order to accurately simulate these flow features. The HPCC program is relying heavily on parallel computers. A Navier-Stokes solver (POVERFLOW) utilizing the Baldwin-Lomax algebraic turbulence model was developed and tested on a 128-node Intel iPSC/860. Algebraic turbulence models run very fast, and give good results for many flowfields. For complex flowfields such as those mentioned above, however, they are often inadequate. It was therefore deemed that a two-equation turbulence model will be required for the HPA computations. The k-epsilon two-equation turbulence model was implemented on the Intel iPSC/860. Both the Chien low-Reynolds-number model and a generalized wall-function formulation were included. Author (revised)

KINEMATICS AND CONSTRAINTS ASSOCIATED WITH SWASHPLATE BLADE PITCH CONTROL
Jane A. Leyland Mar. 1993 35 p
(RTOP 505-61-51)
(NASA-TM-102265; A-90033; NAS 1.15:102265) Avail: CASI HC A03/MF A01

An important class of techniques to reduce helicopter vibration is based on using a Higher Harmonic controller to optimally define the Higher Harmonic blade pitch. These techniques typically require solution of a general optimization problem requiring the determination of a control vector which minimizes a performance index where functions of the control vector are subject to inequality constraints. Six possible constraint functions associated with swashplate blade pitch control were identified and defined. These functions constrain: (1) blade pitch Fourier Coefficients expressed in the Rotating System, (2) blade pitch Fourier Coefficients expressed in the Nonrotating System, (3) stroke of the individual actuators expressed in the Nonrotating System, (4) blade pitch expressed as a function of blade azimuth and actuator stroke, (5) time rate-of-change of the aforementioned parameters, and (6) required actuator power. The aforementioned constraints and the associated kinematics of swashplate blade pitch control by means of the strokes of the individual actuators are documented.

A multi-engine aircraft, with some or all of the flight control system inoperative, may use engine thrust for control. NASA Dryden has conducted a study of the capability and techniques for this emergency flight control method for the F-15 airplane. With an augmented control system, engine thrust, along with appropriate feedback parameters, is used to control flightpath and bank angle. Extensive simulation studies were followed by flight tests. The principles of throttles only control, the F-15 airplane, the augmented system, and the flight results including actual landings with throttles-only control are discussed. Author (revised)

Accurate prediction of airframe/actuation coupling is required by the imposing demands of modern flight control systems. In particular, for agility enhancement at high angle of attack and low dynamic pressure, structural integration characteristics such as hinge moments, effective actuator stiffness, and airframe/control surface damping can have a significant effect on stability predictions. Actuator responses are customarily represented with low-order transfer functions matched to actuator test data, and control surface stiffness is often modeled as a linear spring. The inclusion of the physical properties of actuation and its installation on the airframe is therefore addressed using detailed actuator models which consider the physical, electrical, and mechanical elements of actuation. The aeroservoelastic analysis procedure is described in which the actuators are modeled as

detailed high-order transfer functions and as approximate low-order transfer functions. The impacts of unsteady aerodynamic modeling on aeroservoelastic stability are also investigated by varying the order of approximation, or number of aerodynamic lag states, in the analysis. Test data from a thrust-vectoring configuration of an F/A-18 aircraft are compared to predictions to determine the effects on accuracy as a function of modeling complexity. Author (revised)

PILOTING VERTICAL FLIGHT AIRCRAFT: A CONFERENCE ON FLYING QUALITIES AND HUMAN FACTORS

Christopher L. Blanken, ed. and Matthew S. Whalley, ed. (Army Aviation Systems Command, Moffett Field, CA.) Jul. 1993 488 p Workshop held at San Francisco, CA, 20-22 Jan. 1993

(RTOP 505-59-52)

(NASA-CP-3220; A-93074; NAS 1.55:3220) Avail: CASI HC A21/MF A04

This document contains papers from a specialists' meeting entitled 'Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors.' Vertical flight aircraft, including helicopters and a variety of Vertical Takeoff and Landing (VTOL) concepts, place unique requirements on human perception, control, and performance for the conduct of their design missions. The intent of this conference was to examine, for these vehicles, advances in: (1) design of flight control systems for ADS-33C standards; (2) assessment of human factors influences of cockpit displays and operational procedures; (3) development of VTOL design and operational criteria; and (4) development of theoretical methods or models for predicting pilot/vehicle performance and mission suitability. A secondary goal of the conference was to provide an initial venue for enhanced interaction between human factors and handling qualities specialists. For individual titles, see N94-13295 through N94-13325.

ADS-33C RELATED HANDLING QUALITIES RESEARCH PERFORMED USING THE NRC BELL 205 AIRBORNE SIMULATOR

J. Murray Morgan and Stewart W. Baillie *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 3-15 (For primary document see N94-13294 02-08)

Avail: CASI HC A03/MF A04

Over 10 years ago a project was initiated by the U.S. Army AVSCOM to update the military helicopter flying qualities specification MIL-8501-A. While not yet complete, the project reached a major milestone in 1989 with the publication of an Airworthiness Design Standard, ADS-33C. The 8501 update project initially set out to identify critical gaps in the requisite data base and then proceeded to fill them using a variety of directed research studies. The magnitude of the task required that it become an international effort: appropriate research studies were conducted in Germany, the UK and Canada as well as in the USA. Canadian participation was supported by the Department of National Defence (DND) through the Chief of Research and Development. Both ground based and in-flight simulation were used to study the defined areas and the Canadian Bell 205-A1 variable stability helicopter was used extensively as one of the primary research tools available for this effort. This paper reviews the involvement of the Flight Research Laboratory of the National Research Council of Canada in the update project, it describes the various experiments conducted on the Airborne Simulator, it notes significant results obtained and describes ongoing research associated with the project. MIL-H-8501B: APPLICATION TO SHIPBOARD TERMINAL OPERATIONS

A. N. Cappetta and J. B. Johns (Army Aviation Systems Command, Moffett Field, CA.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 17-36 (For primary document see N94-13294 02-08)

Avail: CASI HC A03/MF A04

The philosophy and structure of the proposed U.S. Military Specification for Handling Qualities Requirements for Military Rotorcraft, MIL-H-8501B, are presented with emphasis on shipboard terminal operations. The impact of current and future naval operational requirements on the selection of appropriate combinations of basic vehicle dynamics and usable cue environments are identified. An example 'walk through' of MIL-H-8501B is conducted from task identification to determination of stability and control requirements. For selected basic vehicle dynamics, criteria as a function of input/response magnitude are presented. Additionally, rotorcraft design development implications are discussed. Author

DESIGN CRITERIA FOR INTEGRATED FLIGHT/PROPULSION CONTROL SYSTEMS FOR STOVL FIGHTER AIRCRAFT

James A. Franklin *In its* Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 37-5 (For primary document see N94-13294 02-08)

Avail: CASI HC A03/MF A04

As part of NASA's program to develop technology for short takeoff and vertical landing (STOVL) fighter aircraft, control system designs have been developed for a conceptual STOVL aircraft. This aircraft is representative of the class of mixed-flow remote-lift concepts that was identified as the preferred design approach by the US/UK STOVL Joint Assessment and Ranking Team. The control system designs have been evaluated throughout the powered-lift flight envelope on Ames Research Center's Vertical Motion Simulator. Items assessed in the control system evaluation were: maximum control power used in transition and vertical flight, control system dynamic response associated with thrust transfer for attitude control, thrust margin in the presence of ground effect and hot gas ingestion, and dynamic thrust response for the engine core. Effects of wind, turbulence, and ship airwake disturbances are incorporated in the evaluation. Results provide the basis for a reassessment of existing flying qualities design criteria applied to STOVL aircraft. Author

A PERSPECTIVE ON THE FAA APPROVAL PROCESS: INTEGRATING ROTORCRAFT DISPLAYS, CONTROLS AND WORKLOAD

David L. Green, Jake Hart (American Eurocopter Corp., Grand Prarie, TX.), and Peter Hwoschinsky (Federal Aviation Administration, Washington, DC.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 59-68 (For primary document see N94-13294 02-08)

Avail: CASI HC A02/MF A04

The FAA is responsible for making the determination that a helicopter is safe for IFR operations in the National Airspace System (NAS). This involves objective and subjective evaluations of cockpit displays, flying qualities, procedures and human factors as they affect performance and workload. After all of the objective evaluations are completed, and all Federal Regulations have been met, FAA pilots make the final subjective judgement as to suitability for use by civil pilots in the NAS. The paper uses the flying qualities and pilot workload characteristics of a small helicopter to help examine the FAA pilot's involvement in this process. The result highlights the strengths of the process and its importance to the approval of new aircraft and equipments for civil IFR helicopter applications. The paper also identifies opportunities for improvement. Author

SOME LESSONS LEARNED IN THREE YEARS WITH ADS-33C

David L. Key, Chris L. Blanken, and Roger H. Hoh (Hoh Aeronautics, Inc., Lomita, CA.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 69-89 (For primary document see N94-13294 02-08)

Avail: CASI HC A03/MF A04

Three years of using the U.S. Army's rotorcraft handling qualities specification, Aeronautical Design Standard - 33, has shown it to be surprisingly robust. It appears to provide an excellent basis for design and for assessment, however, as the subtleties become more well understood, several areas needing refinement became apparent. Three responses to these needs have been documented in this paper: (1) The yaw-axis attitude quickness for hover target acquisition and tracking can be relaxed slightly. (2) Understanding and application of criteria for degraded visual environments needed elaboration. This and some guidelines for testing to obtain visual cue ratings have been documented. (3) The flight test maneuvers were an

innovation that turned out to be very valuable. Their extensive use has made it necessary to tighten definitions and testing guidance. This was accomplished for a good visual environment and is underway for degraded visual environments. Author

INVESTIGATION OF THE EFFECTS OF BANDWIDTH AND TIME DELAY ON HELICOPTER ROLL-AXIS HANDLING QUALITIES

Heinz-Juergen Pausder and Chris L. Blanken (Army Aviation Systems Command, Moffett Field, CA.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 91-110 (For primary document see N94-13294 02-08)

Avail: CASI HC A03/MF A04

Several years of cooperative research conducted under the U.S./German Memorandum of Understanding (MOU) in helicopter flight control has recently resulted in a successful handling qualities study. The focus of this cooperative research has been the effects on handling qualities due to time delays in combination with a high bandwidth vehicle. The jointly performed study included the use of U.S. ground-based simulation and German in-flight simulation facilities. The NASA-Ames Vertical Motion Simulator (VMS) was used to develop a high bandwidth slalom tracking task which took into consideration the constraints of the facilities. The VMS was also used to define a range of the test parameters and to perform initial handling qualities evaluations. The flight tests were conducted using DLR's variable-stability BO 105 S3 Advanced Technology Testing Helicopter System (ATTHeS). Configurations included a rate command and an attitude command response system with added time delays up to 160 milliseconds over the baseline and bandwidth values between 1.5 and 4.5 rad/sec. Sixty-six evaluations were performed in about 25 hours of flight time during ten days of testing. The results indicate a need to more tightly constrain the allowable roll axis phase delay for the Level 1 and Level 2 requirements in the U.S. Army's specification for helicopter handling qualities, ADS-33C. A PILOTED SIMULATION INVESTIGATION OF THE NORMAL LOAD FACTOR AND LONGITUDINAL THRUST REQUIRED FOR AIR-TO-AIR ACQUISITION AND TRACKING

Matthew S. Whalley *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 113-130 (For primary document see N94-13294 02-08)

Avail: CASI HC A03/MF A04

A piloted simulation study was performed by the U.S. Army Aeroflightdynamics Directorate to develop insight into the maneuverability requirements for aggressive helicopter maneuvering tasks such as air-to-air combat. Both a conventional helicopter and a helicopter with auxiliary thrust were examined. The aircraft parameters of interest were the normal and longitudinal load factor envelopes. Of particular interest were the mission performance and handling qualities tradeoffs with the parameters of interest. Two air-to-air acquisition and tracking tasks and a return-to-cover task were performed to assess mission performance. Results indicate that without auxiliary thrust, the ownship normal load factor capability needs to match that of the adversary in order to provide satisfactory handling qualities. Auxiliary thrust provides significant handling qualities advantages and can be substituted to some extent for normal load factor capability. Auxiliary thrust levels as low as 0.2 thrust/weight can provide significant handling qualities advantages. Author

THE APPLICATION OF ACTIVE SIDE ARM CONTROLLERS IN HELICOPTERS

R. Knorr, C. Melz, A. Faulkner, and M. Obermayer *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 131-140 (For primary document see N94-13294 02-08)

Avail: CASI HC A02/MF A04

Eurocopter Deutschland (ECD) started simulation trials to investigate the particular problems of Side Arm Controllers (SAC) applied to helicopters. Two simulation trials have been performed. In the first trial, the handling characteristics of a 'passive' SAC and the basic requirements for the application of an 'active' SAC were evaluated in pilot-in-the-loop simulations, performing the tasks in a realistic scenario representing typical phases of a transport mission. The second simulation trial investigated the general control characteristics of the 'active' in comparison to the 'passive' control principle. A description of the SACs developed by ECD and the principle of the 'passive' and 'active' control concept is given, as well as specific ratings for the investigated dynamic and ergonomic parameters effecting SAC characteristics. The experimental arrangements, as well as the trials procedures of both simulation phases, are described and the results achieved are discussed emphasizing the advantages of the 'active' as opposed to the 'passive' SAC concept. This also includes the presentation of some critical aspects still to be improved and proposals to solve them. Author (revised)

ROTORCRAFT FLYING QUALITIES IMPROVEMENT USING ADVANCED CONTROL

D. Walker, I. Postlethwaite, J. Howitt (Defence Research Agency, Bedford, England.), and N. Foster *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 141-155 (For primary document see N94-13294 02-08)

Avail: CASI HC A03/MF A04

We report on recent experience gained when a multivariable helicopter flight control law was tested on the Large Motion Simulator (LMS) at DRA Bedford. This was part of a study into the application of multivariable control theory to the design of full-authority flight control systems for high-performance helicopters. In this paper, we present some of the results that were obtained during the piloted simulation trial and from subsequent off-line simulation and analysis. The performance provided by the control law led to level 1 handling quality ratings for almost all of the mission task elements assessed, both during the real-time and off-line analysis. Author

THE IMPACT OF FLYING QUALITIES ON HELICOPTER OPERATIONAL AGILITY

Gareth D. Padfield, Nick Lappos (Sikorsky Aircraft, Stratford, CT.), and John Hodgkinson (McDonnell-Douglas Corp., Long Beach, CA.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 157-170 (For primary document see N94-13294 02-08)

Avail: CASI HC A03/MF A04

Flying qualities standards are formally set to ensure safe flight and therefore reflect minimum, rather than optimum, requirements. Agility is a flying quality but relates to operations at high, if not maximum, performance. While the quality metrics and test procedures for flying, as covered for example in ADS33C, may provide an adequate structure to encompass agility, they do not currently address flight at high performance. This is also true in the fixed-wing world and a current concern in both communities is the absence of substantiated agility criteria and possible conflicts between flying qualities and high performance. AGARD is sponsoring a working group (WG19) title 'Operational Agility' that deals with these and a range of related issues. This paper is condensed from contributions by the three authors to WG19, relating to flying qualities. Novel perspectives on the subject are presented including the agility factor, that quantifies performance margins in flying qualities terms; a new parameter, based on maneuver acceleration is introduced as a potential candidate for defining upper limits to flying qualities. Finally, a probabilistic analysis of pilot handling qualities ratings is presented that suggests a powerful relationship between inherent airframe flying qualities and operational agility. Author

A FOUR-AXIS HAND CONTROLLER FOR HELICOPTER FLIGHT CONTROL

Joe DeMaio *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 171-175 (For primary document see N94-13294 02-08)

Avail: CASI HC A01/MF A04

A proof-of-concept hand controller for controlling lateral and longitudinal cyclic pitch, collective pitch and tail rotor thrust was developed. The purpose

of the work was to address problems of operator fatigue, poor proprioceptive feedback and cross-coupling of axes associated with many four-axis controller designs. The present design is an attempt to reduce cross-coupling to a level that can be controlled with breakout force, rather than to eliminate it entirely. The cascaded design placed lateral and longitudinal cyclic in their normal configuration. Tail rotor thrust was placed atop the cyclic controller. A left/right twisting motion with the wrist made the control input. The axis of rotation was canted outboard (clockwise) to minimize cross-coupling with the cyclic pitch axis. The collective control was a twist grip, like a motorcycle throttle. Measurement of the amount of cross-coupling involved in pure, single-axis inputs showed cross coupling under 10 percent of full deflection for all axes. This small amount of cross-coupling could be further reduced with better damping and force gradient control. Fatigue was not found to be a problem, and proprioceptive feedback was adequate for all flight tasks executed. Author

IN-FLIGHT SIMULATION OF HIGH AGILITY THROUGH ACTIVE CONTROL: TAMING COMPLEXITY BY DESIGN
Gareth D. Padfield and Roy Bradley (Caledonian Univ., Glasgow, Scotland.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 177-195 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

The motivation for research into helicopter agility stems from the realization that marked improvements relative to current operational types are possible, yet there is a dearth of useful criteria for flying qualities at high performance levels. Several research laboratories are currently investing resources in developing second generation airborne rotorcraft simulators. The UK's focus has been the exploitation of agility through active control technology (ACT); this paper reviews the results of studies conducted to date. The conflict between safety and performance in flight research is highlighted and the various forms of safety net to protect against system failures are described. The role of the safety pilot, and the use of actuator and flight envelope limiting are discussed. It is argued that the deep complexity of a research ACT system can only be tamed through a requirement specification assembled using design principles and cast in an operational simulation form. Work along these lines conducted at DRA is described, including the use of the Jackson System Development method and associated Ada simulation. Author

COMPATIBILITY OF INFORMATION AND MODE OF CONTROL: THE CASE FOR NATURAL CONTROL SYSTEMS
Dean H. Owen *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 199-204 (For primary document see N94-13294 02-08)
Avail: CASI HC A02/MF A04

The operation of control systems has been determined largely by mechanical constraints. Compatibility with the characteristics of the operator is a secondary consideration, with the result that control may never be optimal, control workload may interfere with performance of secondary tasks, and learning may be more difficult and protracted than necessary. With the introduction of a computer in the control loop, the mode of operation can be adapted to the operator, rather than vice versa. The concept of natural control is introduced to describe a system that supports control of the information used by the operator in achieving an intended goal. As an example, control of speed during simulated approach to a pad by helicopter pilots is used to contrast path-speed control with direct control of global optical flow-pattern information. Differences are evidenced in the performance domains of control activity, speed, and global optical flow velocity. Derived from text

A MODEL FOR ROTORCRAFT FLYING QUALITIES STUDIES
Manoj Mittal and Mark F. Costello *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 205-220 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

This paper outlines the development of a mathematical model that is expected to be useful for rotorcraft flying qualities research. A computer model is presented that can be applied to a range of different rotorcraft configurations. The algorithm computes vehicle trim and a linear state-space model of the aircraft. The trim algorithm uses non linear optimization theory to solve the nonlinear algebraic trim equations. The linear aircraft equations consist of an airframe model and a flight control system dynamic model. The airframe model includes coupled rotor and fuselage rigid body dynamics and aerodynamics. The aerodynamic model for the rotors utilizes blade element theory and a three state dynamic inflow model. Aerodynamics of the fuselage and fuselage empennages are included. The linear state-space description for the flight control system is developed using standard block diagram data. Author

INTERPRETED COOPER-HARPER FOR BROADER USE
David L. Green, Hal Andrews (Naval Air Systems Command, Washington, DC.), and Donald W. Gallagher (Federal Aviation Administration, Atlantic City, NJ.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 221-234 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

The current aircraft assessment process typically makes extensive use of operational personnel during simulations and operational evaluations, with increased emphasis on evaluating the many pilot and/or operator/aircraft control loops. The need for a crew assessment in this broader arena has produced a variety of rating scales. The Cooper-Harper Rating Scale is frequently misused and routinely overlooked in the process, for these applications often extend the scale's use beyond its originally intended application. This paper agrees with the broader application of the Cooper-Harper Rating Scale and presents a concept for the development of a 'use unique' Interpreted Cooper-Harper Scale to help achieve this objective. This interpreted scale concept was conceived during efforts to support an FAA evaluation of a night vision enhancement system. It includes descriptive extensions, which are faithful to the intent of the current Cooper-Harper Scale and should provide the kind of detail that has historically been provided by trained test pilots in their explanatory comments. IMPROVEMENTS IN HOVER DISPLAY DYNAMICS FOR A COMBAT HELICOPTER
Jeffrey A. Schroeder and Michelle M. Eshow (Army Aviation Systems Command, Moffett Field, CA.) *In its* Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 235-250 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

This paper describes a piloted simulation conducted on the NASA Ames Vertical Motion Simulator. The objective of the experiment was to investigate the handling qualities benefits attainable using new display law design methods for hover displays. The new display laws provide improved methods to specify the behavior of the display symbol that predicts the vehicle's ground velocity in the horizontal plane; it is the primary symbol that the pilot uses to control aircraft horizontal position. The display law design was applied to the Apache helmet-mounted display format, using the Apache vehicle dynamics to tailor the dynamics of the velocity predictor symbol. The representations of the Apache vehicle used in the display design process and in the simulation were derived from flight data. During the simulation, the new symbol dynamics were seen to improve the pilots' ability to maneuver about hover in poor visual cuing environments. The improvements were manifested in pilot handling qualities ratings and in measured task performance. The paper details the display design techniques, the experiment design and conduct, and the results. Author

THE DEVELOPMENT AND POTENTIAL OF INVERSE SIMULATION FOR THE QUANTITATIVE ASSESSMENT OF HELICOPTER HANDLING QUALITIES
Roy Bradley and Douglas G. Thomson *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities

and Human Factors Jul. 1993 p 251-263 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

In this paper it is proposed that inverse simulation can make a positive contribution to the study of handling qualities. It is shown that mathematical descriptions of the MTEs (Mission Task Elements) defined in ADS-33C may be used to drive an inverse simulation thereby generating, from an appropriate mathematical model, the controls and states of a subject helicopter flying it. By presenting the results of such simulations it is shown that, in the context of inverse simulation, the attitude quickness parameters given in ADS-33C are independent of vehicle configuration. An alternative quickness parameter, associated with the control displacements required to fly the MTE is proposed, and some preliminary results are presented. Author

AN ANALYTIC MODELING AND SYSTEM IDENTIFICATION STUDY OF ROTOR/FUSELAGE DYNAMICS AT HOVER
Steven W. Hong and H. C. Curtiss, Jr. (Princeton Univ., NJ.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 265-286 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

A combination of analytic modeling and system identification methods have been used to develop an improved dynamic model describing the response of articulated rotor helicopters to control inputs. A high-order linearized model of coupled rotor/body dynamics including flap and lag degrees of freedom and inflow dynamics with literal coefficients is compared to flight test data from single rotor helicopters in the near hover trim condition. The identification problem was formulated using the maximum likelihood function in the time domain. The dynamic model with literal coefficients was used to generate the model states, and the model was parametrized in terms of physical constants of the aircraft rather than the stability derivatives, resulting in a significant reduction in the number of quantities to be identified. The likelihood function was optimized using the genetic algorithm approach. This method proved highly effective in producing an estimated model from flight test data which included coupled fuselage/rotor dynamics. Using this approach it has been shown that blade flexibility is a significant contributing factor to the discrepancies between theory and experiment shown in previous studies. Addition of flexible modes, properly incorporating the constraint due to the lag dampers, results in excellent agreement between flight test and theory, especially in the high frequency range. The present study used a rotorcraft simulator to examine descents-to-hover at landing pads with one of three approach lighting configurations. The impact of simulator platform motion upon descents to hover was also examined. The results showed that the configuration with the most useful optical information led to the slowest final approach speeds, and that pilots found this configuration, together with the presence of simulator platform motion, most desirable. The results also showed that platform motion led to higher rates of approach to the landing pad in some cases. Implications of the results for the design of vertiport approach paths are discussed. Work in our laboratory suggests that pilots can extract temporal range information (i.e., the time to pass a given waypoint) directly from out-the-window motion information. This extraction does not require the use of velocity or distance, but rather operates solely on a 2-D motion cue. In this paper, we present the mathematical derivation of this information, psychophysical evidence of human observers' sensitivity, and possible advantages and limitations of basing vehicle control on this parameter. VISUAL CUEING CONSIDERATIONS IN NAP-OF-THE-EARTH HELICOPTER FLIGHT HEAD-SLAVED HELMET-MOUNTED DISPLAYS **c54**
Arthur J. Grunwald and Silvia Kohn (Technion - Israel Inst. of Engineering, Haifa.) *In its* Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 315-327 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

The pilot's ability to derive Control-Oriented Visual Field Information from teleoperated Helmet-Mounted displays in Nap-of-the-Earth flight, is investigated. The visual field with these types of displays, commonly used in Apache and Cobra helicopter night operations, originates from a relatively narrow field-of-view Forward Looking Infrared Radiation Camera, gimbal-mounted at the nose of the aircraft and slaved to the pilot's line-of-sight, in order to obtain a wide-angle field-of-regard. Pilots have encountered considerable difficulties in controlling the aircraft by these devices. Experimental simulator results presented here indicate that part of these difficulties can be attributed to head/camera slaving system phase lags and errors. In the presence of voluntary head rotation, these slaving system imperfections are shown to impair the Control-Oriented Visual Field Information vital in vehicular control, such as the perception of the anticipated flight path or the vehicle yaw rate. Since, in the presence of slaving system imperfections, the pilot will tend to minimize head rotation, the full wide-angle field-of-regard of the line-of-sight slaved Helmet-Mounted Display, is not always fully utilized. HANDLING QUALITIES EFFECTS OF DISPLAY LATENCY **c06**
David W. King *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 329-340 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

Display latency is the time delay between aircraft response and the corresponding response of the cockpit displays. Currently, there is no explicit specification for allowable display lags to ensure acceptable aircraft handling qualities in instrument flight conditions. This paper examines the handling qualities effects of display latency between 70 and 400 milliseconds for precision instrument flight tasks of the V-22 Tiltrotor aircraft. Display delay effects on the pilot control loop are analytically predicted through a second order pilot crossover model of the V-22 lateral axis, and handling qualities trends are evaluated through a series of fixed-base piloted simulation tests. The results show that the effects of display latency for flight path tracking tasks are driven by the stability characteristics of the attitude control loop. The data indicate that the loss of control damping due to latency can be simply predicted from knowledge of the aircraft's stability margins, control system lags, and required control bandwidths. Based on the relationship between attitude control damping and handling qualities ratings, latency design guidelines are presented. In addition, this paper presents a design philosophy, supported by simulation data, for using flight director display augmentation to suppress the effects of display latency for delays up to 300 milliseconds. EFFECTS OF SIMULATOR MOTION AND VISUAL CHARACTERISTICS ON ROTORCRAFT HANDLING QUALITIES EVALUATIONS
David G. Mitchell and Daniel C. Hart (Army Aviation Systems Command, Moffett Field, CA.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 341-359 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

The pilot's perceptions of aircraft handling qualities are influenced by a combination of the aircraft dynamics, the task, and the environment under which the evaluation is performed. When the evaluation is performed

in a groundbased simulator, the characteristics of the simulation facility also come into play. Two studies were conducted on NASA Ames Research Center's Vertical Motion Simulator to determine the effects of simulator characteristics on perceived handling qualities. Most evaluations were conducted with a baseline set of rotorcraft dynamics, using a simple transfer-function model of an uncoupled helicopter, under different conditions of visual time delays and motion command washout filters. Differences in pilot opinion were found as the visual and motion parameters were changed, reflecting a change in the pilots' perceptions of handling qualities, rather than changes in the aircraft model itself. The results indicate a need for tailoring the motion washout dynamics to suit the task. Visual-delay data are inconclusive but suggest that it may be better to allow some time delay in the visual path to minimize the mismatch between visual and motion, rather than eliminate the visual delay entirely through lead compensation. PRIMARY DISPLAY LATENCY CRITERIA BASED ON FLYING QUALITIES AND PERFORMANCE DATA
John D. Funk, Jr., Corin P. Beck, and John B. Johns (Army Aviation Systems Command, Moffett Field, CA.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 361-374 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

With a pilots' increasing use of visual cue augmentation, much requiring extensive pre-processing, there is a need to establish criteria for new avionics/display design. The timeliness and synchronization of the augmented cues is vital to ensure the performance quality required for precision mission task elements (MTEs) where augmented cues are the primary source of information to the pilot. Processing delays incurred while transforming sensor-supplied flight information into visual cues are unavoidable. Relationships between maximum control system delays and associated flying qualities levels are documented in MIL-F-83300 and MIL-F-8785. While cues representing aircraft status may be just as vital to the pilot as prompt control response for operations in instrument meteorological conditions, presently, there are no specification requirements on avionics system latency. To produce data relating avionics system latency to degradations in flying qualities, the Navy conducted two simulation investigations. During the investigations, flying qualities and performance data were recorded as simulated avionics system latency was varied. Correlated results of the investigation indicates that there is a detrimental impact of latency on flying qualities. Analysis of these results and consideration of key factors influencing their application indicate that: (1) Task performance degrades and pilot workload increases as latency is increased. Inconsistency in task performance increases as latency increases. (2) Latency reduces the probability of achieving Level 1 handling qualities with avionics system latency as low as 70 ms. (3) The data suggest that the achievement of desired performance will be ensured only at display latency values below 120 ms. (4) These data also suggest that avoidance of inadequate performance will be ensured only at display latency values below 150 ms. Author

HUMAN FACTOR IMPLICATIONS OF THE EUROCOPTER AS332L-1 SUPER PUMA COCKPIT **c54**
R. Randall Padfield *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 377-392 Presented at the 15th European Rotorcraft Forum, Amsterdam, The Netherlands, 12-15 Sep. 1989 Previously announced in AIAA as A91-45400 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

The purpose of this paper is to identify and describe some of the human factor problems which can occur in the cockpit of a modern civilian helicopter. After examining specific hardware and software problems in the cockpit design of the Eurocopter (Aerospatiale) AS332L-1 Super Puma, the author proposes several principles that can be used to avoid similar human factors problems in the design of future cockpits. These principles relate to the use and function of warning lights, the design of autopilots in two-pilot aircraft, and the labeling of switches and warning lights, specifically with respect to abbreviations and translations from languages other than English. In the final section of the paper, the author describes current trends in society which he suggests should be taken into consideration when designing future aircraft cockpits. Author

PILOTING CONSIDERATIONS FOR TERMINAL AREA OPERATIONS OF CIVIL TILTWING AND TILTROTOR AIRCRAFT
William S. Hindson, Gordon H. Hardy, George E. Tucker, and William A. Decker *In its* Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 393-410 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

The existing body of research to investigate airworthiness, performance, handling, and operational requirements for STOL and V/STOL aircraft was reviewed for its applicability to the tiltrotor and tiltwing design concepts. The objective of this study was to help determine the needs for developing civil certification criteria for these aircraft concepts. Piloting tasks that were considered included configuration and thrust vector management, glidepath control, deceleration to hover, and engine failure procedures. Flight control and cockpit display systems that have been found necessary to exploit the low-speed operating characteristics of these aircraft are described, and beneficial future developments are proposed. This paper addresses the design and pilot evaluation of the Core Automatic Flight Control System (AFCS) for the Reconnaissance/Attack Helicopter (RAH-66) Comanche. During the period from November 1991 through February 1992, the RAH-66 Comanche control laws were evaluated through a structured pilot acceptance test using a motion base simulator. Design requirements, descriptions of the control law design, and handling qualities data collected from ADS-33 maneuvers are presented. Author

DESIGN AND PILOT EVALUATION OF THE RAH-66 COMANCHE SELECTABLE CONTROL MODES
Phillip J. Gold and James B. Dryfoos (Boeing Defense and Space Group, Philadelphia, PA.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 419-431 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

The RAH-66 Comanche helicopter has been designed to possess superior handling qualities over a wide range of flight conditions. The control laws have been tailored to satisfy the requirements of ADS-33C and the Weapon System Specification (WSS). This paper addresses the design of the Comanche Selectable Mode control laws (Velocity Stabilization/Hover Hold and Altitude Hold), which provide the additional stabilization and control augmentation needed when flying in a Degraded Visual Environment (DVE). An overview of the RAH-66 control laws is presented, including a detailed description of the Selectable Modes design. The primary focus of this paper is the results of piloted evaluation of these control laws in the Boeing motionbase simulator. These tests substantiate the detailed design of the Comanche Selectable Mode control laws. All tested DVE tasks (ADS-33C, sections 4.4 and 4.5) were rated Level 1. Other evaluation tasks confirmed the mission suitability of the control system. These control laws are ready for formal ADS-33C compliance testing in the Sikorsky Full Mission Simulator (FMS). EVALUATION OF TWO COCKPIT DISPLAY CONCEPTS FOR CIVIL TILTROTOR INSTRUMENT OPERATIONS ON STEEP APPROACHES **c06**
William A. Decker, Richard S. Bray, Rickey C. Simmons, and George E.

Tucker *In its* Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 433-452 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

A piloted simulation experiment was conducted using the NASA Ames Research Center Vertical Motion Simulator to evaluate two cockpit display formats designed for manual control on steep instrument approaches for a civil transport tiltrotor aircraft. The first display included a four-cue (pitch, roll, power lever position, and nacelle angle movement prompt) flight director. The second display format provided instantaneous flight path angle information together with other symbols for terminal area guidance. Pilots evaluated these display formats for an instrument approach task which required a level flight conversion from airplane-mode flight to helicopter-mode flight while decelerating to the nominal approach airspeed. Pilots tracked glide slopes of 6, 9, 15 and 25 degrees, terminating in a hover for a vertical landing on a 150 feet square vertipad. Approaches were conducted with low visibility and ceilings and with crosswinds and turbulence, with all aircraft systems functioning normally and were carried through to a landing. Desired approach and tracking performance was achieved with generally satisfactory handling qualities using either display format on glide slopes up through 15 degrees. Evaluations with both display formats for a 25 degree glide slope revealed serious problems with glide slope tracking at low airspeeds in crosswinds and the loss of the intended landing spot from the cockpit field of view. FLIGHT TESTING AND FREQUENCY DOMAIN ANALYSIS FOR ROTORCRAFT HANDLING QUALITIES CHARACTERISTICS
Johnnie A. Ham, Charles K. Gardner, and Mark B. Tischler (Army Aviation Systems Command, Moffett Field, CA.) *In* NASA. Ames Research Center, Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 453-469 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

A demonstration of frequency domain flight testing techniques and analyses was performed on a U.S. Army OH-58D helicopter in support of the OH-58D Airworthiness and Flight Characteristics Evaluation and the Army's development and ongoing review of Aeronautical Design Standard 33C, Handling Qualities Requirements for Military Rotorcraft. Hover and forward flight (60 knots) tests were conducted in 1 flight hour by Army experimental test pilots. Further processing of the hover data generated a complete database of velocity, angular rate, and acceleration frequency responses to control inputs. A joint effort was then undertaken by the Airworthiness Qualification Test Directorate (AQTD) and the U.S. Army Aeroflightdynamics Directorate (AFDD) to derive handling qualities information from the frequency response database. A significant amount of information could be extracted from the frequency domain database using a variety of approaches. This report documents numerous results that have been obtained from the simple frequency domain tests; in many areas, these results provide more insight into the aircraft dynamics that affect handling qualities than to traditional flight tests. The handling qualities results include ADS-33C bandwidth and phase delay calculations, vibration spectral determinations, transfer function models to examine single axis results, and a six degree of freedom fully coupled state space model. The ability of this model to accurately predict aircraft responses was verified using data from pulse inputs. This report also documents the frequency-sweep flight test technique and data analysis used to support the tests. Author

PRELIMINARY DESIGN FEATURES OF THE RASCAL: A NASA /ARMY ROTORCRAFT IN-FLIGHT SIMULATOR **c09**
Edwin W. Aiken, Robert A. Jacobsen, Michelle M. Eshow (Army Aviation Systems Command, Moffett Field, CA.), William S. Hindson, and Douglas H. Doane *In its* Piloting Vertical Flight Aircraft: A Conference on Flying Qualities and Human Factors Jul. 1993 p 471-486 (For primary document see N94-13294 02-08)
Avail: CASI HC A03/MF A04

Salient design features of a new NASA/Army research rotorcraft - the Rotorcraft-Aircrew Systems Concepts Airborne Laboratory (RASCAL) - are described. Using a UH-60A Black Hawk helicopter as a baseline vehicle, the RASCAL will be a flying laboratory capable of supporting the research requirements of major NASA and Army guidance, control, and display research programs. The paper describes the research facility requirements of these programs together with other critical constraints on the design of the research system, including safety-of-flight. Research program schedules demand a phased development approach, wherein specific research capability milestones are met and flight research projects are flown throughout the complete development cycle of the RASCAL. This development approach is summarized, and selected features of the research system are described. The research system includes a full-authority, programmable, fault-tolerant/fail-safe, fly-by-wire flight control system and a real-time obstacle detection and avoidance system which will generate low-altitude guidance commands to the pilot on a wide field-of-view, color helmet-mounted display. ROLLING MOMENT CONTROL IN THE NAL 10 cm X 10 cm MAGNETIC SUSPENSION AND BALANCE SYSTEM [KOUGIKEN 10 CM X 10 CM JIRYOKU SHIJU TENBIN SOUCHI YOKOYURE SEIGYO NITSUITE]
Hideo Sawada, Hisashi Suenaga, Takayuki Suzuki (Musashi Inst. of Tech., Tokyo, Japan.), and Nobukazu Ikeda (Musashi Inst. of Tech., Tokyo, Japan.) Jun. 1992 17 p In JAPANESE
(NAL-TR-1164; JTN-93-80494) Avail: CASI HC A03/MF A01

To have control the rolling moment acting on a model suspended in National Aerospace Laboratory (NAL) 10 cm x 10 cm Magnetic Suspension and Balance System (MSBS), two extra pairs of small magnets were attached perpendicular to the model axis at both the front and rear sides of it. Side force, yawing moment, and rolling moment acting on the model are controlled by the currents passing through the system's four side coils. Test results indicate the roll angle is suitably controlled using this method. An analytical approximation for estimating the rolling moment with the existing arrangement of magnetic moments and charges is described. This approximation correlates well with several experimental results. The NAL MSBS has the capability of controlling model motion with six degrees of freedom.

KNOWLEDGE-BASED PROCESSING FOR AIRCRAFT FLIGHT CONTROL Final Report, period ending 17 Oct. 1991
John H. Painter 17 Oct. 1991 8 p
(Grant NAG1-1066)
(NASA-CR-194074; NAS 1.26:194074) Avail: CASI HC A02/MF A01

The purpose is to develop algorithms and architectures for embedding artificial intelligence in aircraft guidance and control systems. With the approach adopted, AI-computing is used to create an outer guidance loop for driving the usual aircraft autopilot. That is, a symbolic processor monitors the operation and performance of the aircraft. Then, based on rules and other stored knowledge, commands are automatically formulated for driving the autopilot so as to accomplish desired flight operations. The focus is on developing a software system which can respond to linguistic instructions, input in a standard format, so as to formulate a sequence of simple commands to the autopilot. The instructions might be a fairly complex flight clearance, input either manually or by data-link. Emphasis is on a software system which responds much like a pilot would, employing not only precise computations, but, also, knowledge which is less precise, but more like common-sense. The approach is based on prior work to develop a generic 'shell' architecture for an AI-processor, which may be tailored to many applications by describing the application in appropriate processor data bases (libraries). Such descriptions include numerical models of the aircraft and flight control system, as well as symbolic (linguistic) descriptions of flight operations, rules, and tactics. Author (revised)

MEASUREMENTS OF WING AND FIN BUFFETING ON THE STANDARD DYNAMICS MODEL
S. J. Zan May 1993 82 p
(IAR-AN-76; NRC-32158; CTN-93-60761) Avail: CASI HC A05/MF A01

A wind tunnel investigation was conducted on wing and fin buffeting

measured on the Standard Dynamics Model, a generic fighter aircraft configuration. Buffeting was investigated for three modes: the fin bending mode and the wing symmetric and antisymmetric bending modes. Tests were performed at four wind speeds corresponding to reduced frequencies ranging from 0.6 to 1.5 for the wings and 0.9 to 1.8 for the fin. The angle of attack ranged from zero to 53 deg and the sideslip angle ranged from minus 10 deg to plus 10 deg. The model was tested with and without strakes. The data are presented in terms of the buffet excitation parameter. It was found that the level of fin buffeting exceeded that of wing buffeting by an order of magnitude. This severe fin buffeting arises from the immersion of the fin in the swirling wake of the burst strake and/or forebody vortices. The fin buffet excitation peaked near an angle of attack corresponding to the onset of asymmetrical forebody flow. This excitation was sensitive to the presence of sideslip and to the value of the reduced frequency parameter. The magnitude of the parameter did not exceed 0.003, a limit that was achieved for cases where the excitation arose from the interaction of the strake and wing vortices or simply from separated flow unsteadiness over the wing. INVESTIGATION OF AN AEROELASTIC OSCILLATOR: ANALYSIS OF ONE-DEGREE-OF-FREEDOM GALLOPING WITH COMBINED TRANSLATIONAL AND TORSIONAL EFFECTS
B. W. vanOudheusden Dec. 1992 28 p
(LR-707; ETN-93-94424) Avail: CASI HC A03/MF A01

The investigation was carried out in the framework of a research project on aeroelastic oscillators. The results of literature investigations about the background and analysis of galloping and the construction of a test set up are summarized. Galloping is a type of flow induced vibration, which is caused by aerodynamic instability: the unsteady aerodynamic forces on the oscillating structure can amplify or sustain the vibration. The major assumptions underlying the theory with which galloping is described and an analysis of two types of one degree of freedom galloping are discussed. The purpose of the analysis is to give an insight into the relevant parameters of the phenomenon and the set up. ESA

(NASA-CR-194260; NAS 1.26:194260; MCAT-93-18) Avail: CASI HC A03/MF A01; 2 functional color pages

Attached as appendices to this report are documents describing work performed on the simulation of a landing powered-lift delta wing, the tracking of flow features using overset grids, and the simulation of flaps on the Wright Patterson Lab's fighter-lift-and-control (FLAC) wing. Numerical simulation of a powered-lift landing includes the computation of flow about a delta wing at four fixed heights as well as a simulated landing, in which the delta wing descends toward the ground. Comparison of computed and experimental lift coefficients indicates that the simulations capture the qualitative trends in lift-loss encountered by thrust-vectoring aircraft operating in ground effect. Power spectra of temporal variations of pressure indicate computed vortex shedding frequencies close to the jet exit are in the experimentally observed frequency range; the power spectra of pressure also provide insights into the mechanisms of lift oscillations. Also, a method for using overset grids to track dynamic flow features is described and the method is validated by tracking a moving shock and vortices shed behind a circular cylinder. Finally, Chimera gridding strategies were used to develop pressure coefficient contours for the FLAC wing for a Mach no. of 0.18 and Reynolds no. of 2.5 million. CASI

The Vertical Motion Simulator Familiarization Guide provides a synoptic description of the Vertical Motion Simulator (VMS) and descriptions of the various simulation components and systems. The intended audience is the community of scientists and engineers who employ the VMS for research and development. The concept of a research simulator system is introduced and the building block nature of the VMS is emphasized. Individual sections describe all the hardware elements in terms of general properties and capabilities. Also included are an example of a typical VMS simulation which graphically illustrates the composition of the system and shows the signal flow among the elements and a glossary of specialized terms, abbreviations, and acronyms. (NASA-CR-189560; NAS 1.26:189560; PSI-2090/TR-1140) Avail: CASI HC A08/MF A02

In order to demonstrate the measurement of aerodynamic forces/moments, including the effects of exhaust jets in Magnetic Suspension and Balance System (MSBS) wind tunnels, two propulsion simulator models were developed at Physical Sciences Inc. (PSI). Both the small-scale model (1 in. diameter X 8 in. long) and the large-scale model (2.5 in. diameter X 15 in. long) employed compressed, liquefied carbon dioxide as a propellant. The small-scale simulator, made from a highly magnetizable iron alloy, was demonstrated in the 7 in. MSBS wind tunnel at the University of Southampton. It developed a maximum thrust of approximate 1.3 lbf with a 0.098 in. diameter nozzle and 0.7 lbf with a 0.295 in. diameter nozzle. The Southampton MSBS was able to control the simulator at angles-of attack up to 20 deg. The large-scale simulator was demonstrated to operate in both a steady-state and a pulse mode via a miniaturized solinoid valve. It developed a stable and repeatable thrust of 2.75 lbf over a period of 4s and a nozzle pressure ratio (NPR) of 5. Author (revised)

CONTROL SYSTEM DESIGN OF A CABLE-MOUNTED MODEL USED FOR DYNAMIC WIND TUNNEL TESTING [KEBURU SHIJI DOUTEKI FUUDOU SHIKEN NO TAMENO MOKEI SEIGYOKEI SEKKEI]

Masaaki Yanagihara, Masahiko Nagayasu, Shuuichi Sasa, and Takashi Shimomura Jun. 1992 52 p In JAPANESE
(NAL-TR-1161; JTN-93-80484) Avail: CASI HC A04/MF A01

The control system of a cable-mounted aircraft model used for dynamic wind tunnel testing was designed using the root locus method. Computer simulations were initially performed to evaluate the designed control system, which was then applied to actual wind tunnel tests. Results confirmed the system's suitability, although the control gains required slight tuning. In addition, wind tunnel tests were conducted using the control system to identify the aerodynamic model of the cable-mounted model.

FUTURE DEVELOPMENTS OF THE NLR RESEARCH FLIGHT SIMULATOR

C. J. Jansen 31 Mar. 1992 14 p Presented at the Aeronautical Students Association Simulation Symposium, Haarlem, Netherlands, 20 Mar. 1990
(NLR-TP-92143-U; ETN-93-94345) Avail: CASI HC A03/MF A01

The upgrading program of the flight simulator is overviewed. The period from some years ago, when the simulator had a relatively small motion system and limited vision of the outside world, till the end of 1994 is addressed. The following major improvements which have already been realized are described: the avionics system (this consists of an ARINC bus interface system to couple Electronic Flight Instrument System (EFIS) displays, a programmable EFIS, and a general purpose graphics station); a new fully hydrostatic 6 degrees of freedom motion system with high bandwidth (only 45 deg phase lag at 4 Hz for acceleration commands from the simulator computer); and a high bandwidth digital bus interface system. Upgrades foreseen for the coming two years are also described. These involve increasing the computational power; installation of an F-16 cockpit with g seat; and a visual system with an increased field of view, at least 150 deg horizontal by 60 deg vertical. AIRPORT TERMINALS: OPTIMUM CONFIGURATIONS AND GATE POSITION REQUIREMENT Ph.D. Thesis

J. M. S. J. Bandara Dec. 1989 325 p
(ISBN-0-315-61722-5; CTN-93-60729) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

The level of service method and the minimum cost method are used to determine the number of gate positions required at an airport terminal. The former method is used to calculate the number of gate positions required to provide a given level of reliability. In the latter method, an optimum number of gate positions that will minimize the sum of the cost of gates and the cost of delay to aircraft is obtained. An approximate procedure to determine the deterministic delay to aircraft, based on the information regarding the peaking of the aircraft arrival rate and the number of peaks per day is presented. Closed-form solutions are obtained for the cases of one peak and several identical nonoverlapping peaks, respectively. Given the size of the terminal in terms of the number of aircraft gates, an analytic expression is obtained for the mean passenger walking distance. A continuum expression is used to model passenger walking within the piers or satellites. The optimum geometry in terms of the number of piers or satellites and their sizes is obtained by minimizing the mean walking distance for all the passengers. Statistical parameters suitable for choosing the best configuration for the terminal are suggested. A numerical example to illustrate the selection of the best terminal geometry is presented.

SIMULATOR STUDY OF UNCOUPLED CONTROL FUNCTIONS. USE OF MANUAL POINTING MODES WHEN AIMING AT GROUND TARGETS AND ONCOMING AIRBORNE TARGET

Aake Hyden and Gunnar Hovmark Oct. 1992 54 p
(Contracts FMV-Flyg-82450-87-348-24-001; FMV-Flyg-82450-88-341-73-0)
(FFA-TN-1992-18; ETN-93-94380) Avail: CASI HC A04/MF A01

A number of flight simulator tests were carried out to find whether manually controlled pointing in pitch and yaw would be valuable as a complement to an automatically controlled pointing mode. The results showed that a manual pointing mode will not give a general increase of the aircraft aiming capabilities. Most of the 19 pilots who tried the manual pointing modes in the simulator were quite positive in their opinions, but the aiming results and other results are only slightly better and sometimes not as good as the ones achieved with conventional control. The main advantage of pointing mode over conventional control was that a greater minimum distance to target could be achieved. The risk of confusing the controls, the often longer periods of straight flight paths, the pilots experiencing a higher workload and taking the left hand (and the control grip) away from other important tasks are factors that speak against manual pointing. A GUIDE TO THE DRA 13 FT X 9 FT LOW SPEED WIND TUNNEL FACILITY

M. H. Hunter Apr. 1993 33 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267739; DRA-TR-93014; DRIC-BR-318697) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This Technical Report is intended to provide a guide to the 13 ft. x 9 ft. Low Speed Wind Tunnel Facility. It details the model support and balance assemblies, provides an insight to the instrumentation and computing capabilities, and indicates the different flow visualization techniques available. A description of the tunnel and local facilities is included, along with contact numbers for customers' use. DTIC

This report describes the radiation effect to the CF (Carbon Fiber)/polyimide matrix composite material which will be used for the aerospace plane HOPE (H-2 Orbiting Plane) as a construction material. Results of the electron beam irradiation test, and characteristics measurement of the CF and polyimide composite material tests are described. The electron beam irradiation test was conducted using a 2 MeV electron beam and in a condition of 5 kGy/s in dose rate on the water cooling board at 40 cm below the acceleration tube. A three point bending test was conducted on each of the five samples of the CF/polyimide composite material and polyimide resin simplexes at a test speed of 5 mm/min at a span condition of 80 mm (span ratio 40 for composite material) and 32 mm (span ratio 16 for the resin simplexes). It was concluded that the polyimide resin shows a very high thermal resistance and cross links at a high dose rate of electron beam irradiation. The CF/polyimide composite material using this resin as the matrix show little characteristics change in the ambient temperature and is a material having a superior radiation resistant material. This report describes a concept and key technologies for the modular mesh deployable antenna. The antenna reflector composed of independently manufactured and tested modules is presented. Each module consists of a mesh surface, a cable network, and a deployable truss structure. The cable network comprises three kinds of cables, surface, tie, and back cables. Adjustment of tie cable lengths improves the surface accuracy. Synchronous deployment truss structures are considered as a supporting structure. Their design method, BBM's (Bread Board Model) and deployment analysis are also explained. Author (NASDA)

This report presents an overview of the development of helical truss beams for large space structures which has a high folding efficiency at launch, easily deployed, and has a high structural efficiency in space. The structure, folding and deployment systems, and merits and drawbacks of the helical truss beam are outlined. The trial manufacture of the one fifth scale model of the helical truss beams (basic frame work member size of 3 m in length and 30 mm in diameter), wire spring hinge for joints of frame work, and zip type latching mechanisms for the joints is explained. The results of the study using the trial manufactured units to verify the deployment and folding function and the folded configurations of the helical truss beams are also outlined. Author (NASDA)

This report describes the 6m hexa-link truss type scale model (4 GHz band offset parabolic antenna with a 6m diameter aperture and a 6m focal length) and 2m TETRUS type scale model (12 GHz band offset parabolic antenna with a 1.7m diameter aperture and a 2.2m focal length). Each antenna has electrical and mechanical characteristics similar to those of the large truss-type mesh deployable antenna of the Geostationary Platform (GPF) mobile communication satellites. The antennas were chosen to satisfy the increasing communication demands and requirements for advanced and diversified communication. The microgravity performance verification of these scale models is discussed. Additionally, the following topics are discussed: examples of the structures of GPF-type mobile communication satellite, the hexa-link truss type scale model, and the TETRUS (Tetra Trigonal Prism Truss) type scale model; the orbit of the scale models; and their space verification. Avail: CASI HC A02/MF A01

The use of deployable trusses was analyzed, and related problems were examined. The basic deployment movement of the SHSF (Sliding Hinge Single Fold) was taken as the examination object, and the analysis results were studied. A pulley system which can cope with overloading and deviation from synchronization was adopted. Some trial models were manufactured. The behavior of the truss is controlled by three factors: (1) deployment pattern; (2) element characteristics (such as those of hinges); and (3) the environment of deployment. Only the structural elements which constitute the deployment section were subjected to the examination as it is not necessary to examine the overall SHSF when the frame members of the truss are rigid and in an ideal condition (such as frictionless). The basic concepts of the SHSF--sliding hinge movement via deployment angle, shape change in deployment, and the center of gravity position--and the results of vibration analysis of the SHSF are shown. Avail: CASI HC A02/MF A01

The basic concept of a deployable truss structure was studied. The truss structure introduced here is a one-dimensional box type which employs a simple folding mechanism using telescopic members for stowing. It is suitable for use in the main supporting structures of platform type spacecraft such as geostationary platforms. It is stowed compactly, deploys automatically, and has high rigidity in deployment. By mechanism analyses, the validity of deploying movement was confirmed and the deploying force was estimated. It was found that the deploying driving force could be very in zero gravity conditions. A functional model was fabricated to confirm the structural concept. Author (NASDA)

ORBIT DETERMINATION ERROR ANALYSIS BASED ON THE REQUIREMENTS OF ADEOS MISSION [ADEOS MISSHON YOUKYUU NI MOTOZUKU KIDOU KETTEI GOSA KAISEKI]
Tokyo, Japan National Space Development Agency 31 Mar. 1993 18 p In JAPANESE
(NASDA-CNT-930008; JTN-93-80462) Avail: CASI HC A03/MF A01

A summary of the results of the atmospheric density error analysis and the study on the feasibility of orbit accuracy requirements corresponding to the observation system peculiar to the ILAS (Improved Limb Atmospheric Spectrometer) to be carried onboard the ADEOS (Advanced Earth Observing Satellite) is presented. The atmospheric drag coefficient which is deemed to cause the largest effects on orbit decision accuracy was investigated, and the results are shown. The orbit decision accuracy requirements for ILAS can be evaluated as the tangential altitude (an altitude defined by the perpendicular line from the earth center to the satellite-sun direction vector) error at the time of ILAS observation. The analysis was conducted according to the following procedures: (1) calculation of ADEOS orbit decision accuracy; and (2) conversion of the ADEOS orbit decision error covariance to the altitude error at the time of ILAS observation. Analysis of interplanetary trajectories is a crucial area for both manned and unmanned missions of the Space Exploration Initiative. A deep space maneuver (DSM) can improve a trajectory in much the same way as a planetary swingby. However, instead of using a gravitational field to alter the trajectory, the on-board propulsion system of the spacecraft is used when the vehicle is not near a planet. The purpose is to develop an algorithm to determine where and when to use deep space maneuvers to reduce the cost of a trajectory. The approach taken to solve this problem uses primer vector theory in combination with a non-linear optimizing program to minimize Delta(V). A set of necessary conditions on the primer vector is shown to indicate whether a deep space maneuver will be beneficial. Deep space maneuvers are applied to a round trip mission to Mars to determine their effect on the launch opportunities. Other studies which were performed include cycler trajectories and Mars mission abort scenarios. It was found that the software developed was able to locate quickly DSM's which lower the total Delta(V) on these trajectories. Author (revised)

SEQUENTIAL RANGING: HOW IT WORKS
Harold W. Baugh 15 Jun. 1993 24 p
(Contract NAS7-918)
(NASA-CR-194508; JPL-Publ-93-18; NAS 1.26:194508) Avail: CASI HC A03/MF A01

This publication is directed to the users of data from the Sequential Ranging Assembly (SRA), and to others who have a general interest in range measurements. It covers the hardware, the software, and the processes used in acquiring range data; it does not cover analytical aspects such as the theory of modulation, detection, noise spectral density, and other highly technical subjects. In other words, it covers how ranging is done, but not the details of why it works. The publication also includes an appendix that gives a brief discussion of PN ranging, a capability now under development. Author (revised)

Optical images, such as experimental interferograms, schlieren, and shadowgraphs, are routinely used to identify and locate features in experimental flow fields and for validating computational fluid dynamics (CFD) codes. Interferograms can also be used for comparing experimental and computed integrated densities. By constructing these optical images from flow-field simulations, one-to-one comparisons of computation and experiment are possible. During the period from February 1, 1992, to November 30, 1992, work has continued on the development of CISS (Constructed Interferograms, Schlieren, and Shadowgraphs), a code that constructs images from ideal- and real-gas flow-field simulations. In addition, research connected with the automated film-reading system and the proposed reactivation of the radiation facility has continued.

PAYLOAD/GSE/DATA SYSTEM INTERFACE: USERS GUIDE FOR THE VPF (VERTICAL PROCESSING FACILITY)
28 Sep. 1993 88 p Revised
(Contract NAS10-11400)
(NASA-CR-194385; NAS 1.26:194385; KSC-DL-522-Rev-B) Avail: CASI HC A05/MF A01

Payload/GSE/data system interface users guide for the Vertical Processing Facility is presented. The purpose of the document is three fold. First, the simulated Payload and Ground Support Equipment (GSE)

Data System Interface, which is also known as the payload T-0 (T-Zero) System is described. This simulated system is located with the Cargo Integration Test Equipment (CITE) in the Vertical Processing Facility (VPF) that is located in the KSC Industrial Area. The actual Payload T-0 System consists of the Orbiter, Mobile Launch Platforms (MLPs), and Launch Complex (LC) 39A and B. This is referred to as the Pad Payload T-0 System (Refer to KSC-DL-116 for Pad Payload T-0 System description). Secondly, information is provided to the payload customer of differences between this simulated system and the actual system. Thirdly, a reference guide of the VPF Payload T-0 System for both KSC and payload customer personnel is provided. Author (revised)

Experimental interferograms, schlieren, and shadowgraphs are used for quantitative and qualitative flow-field studies. These images are created by passing light through a flow field, and the recorded intensity patterns are functions of the phase shift and angular deflection of the light. As part of the grant NCC2-583, techniques and software have been developed for obtaining phase shifts from finite-fringe interferograms and for constructing optical images from Computational Fluid Dynamics (CFD) solutions. During the period from 1 Nov. 1992 - 30 Jun. 1993, research efforts have been concentrated in improving these techniques. Author (revised)

TERRESTRIAL ENVIRONMENT (CLIMATIC) CRITERIA GUIDELINES FOR USE IN AEROSPACE VEHICLE DEVELOPMENT, 1993 REVISION
D. L. Johnson, ed. Washington Aug. 1993 458 p Supersedes TM X-64589, TM X-64757, TM X-78118, and TM-82473
(NASA-TM-4511; M-723; NAS 1.15:4511) Avail: CASI HC A20/MF A04

Guidelines on terrestrial environment data specifically applicable in the development of design requirements/specifications for NASA aerospace vehicles and associated equipment development are provided. The primary geographic areas encompassed are the John F. Kennedy Space Center, FL; Vandenberg AFB, CA; Edwards AFB, CA; Michoud Assembly Facility, New Orleans, LA; John C. Stennis Space Center, MS; Lyndon B. Johnson Space Center, Houston, TX; and the White Sands Missile Range, NM. In addition, a section was included to provide information on the general distribution of natural environmental extremes in the conterminous United States that may be needed to specify design criteria in the transportation of space vehicle subsystems and components. A summary of climatic extremes for worldwide operational needs is also included. Although not considered as a specific vehicle design criterion, a section on atmospheric attenuation was added since sensors on certain Earth orbital experiment missions are influenced by the Earth's atmosphere. The latest available information on probable climatic extremes is presented and supersedes information presented in TM X-64589, TM X-64757, TM X-78118, and TM-82473. Information is included on atmospheric chemistry, seismic criteria, and on a mathematical model to predict atmospheric dispersion of aerospace engine exhaust cloud rise and growth. There is also a section on atmospheric cloud phenomena. The information is recommended for use in the development of aerospace vehicle and associated equipment design and operational criteria, unless otherwise stated in contract work specifications. The environmental data are primarily limited to information below 90 km. Author (revised)

STS-55 PAD ABORT: ENGINE 2011 OXIDIZER PREBURNER AUGMENTED SPARK IGNITER CHECK VALVE LEAK Final Report
22 Mar. 1993 132 p
(Contract NAS8-40000)
(NASA-CR-193830; NAS 1.26:193830; RSS-8898) Avail: CASI HC A07/MF A02

The STS-55 initial launch attempt of Columbia (OV102) was terminated on KSC launch pad A March 22, 1993 at 9:51 AM E.S.T. due to violation of an ME-3 (Engine 2011) Launch Commit Criteria (LCC) limit exceedance. The event description and timeline are summarized. Propellant loading was initiated on 22 March, 1993 at 1:15 AM EST. All SSME chill parameters and launch commit criteria (LCC) were nominal. At engine start plus 1.44 seconds, a Failure Identification (FID) was posted against Engine 2011 for exceeding the 50 psia Oxidizer Preburner (OPB) purge pressure redline. The engine was shut down at 1.50 seconds followed by Engines 2034 and 2030. All shut down sequences were nominal and the mission was safely aborted. The OPB purge pressure redline violation and the abort profile/overlay for all three engines are depicted. SSME Avionics hardware and software performed nominally during the incident. A review of vehicle data table (VDT) data and controller software logic revealed no failure indications other than the single FID 013-414, OPB purge pressure redline exceeded. Software logic was executed according to requirements and there was no anomalous controller software operation. Immediately following the abort, a Rocketdyne/NASA failure investigation team was assembled. The team successfully isolated the failure cause to the oxidizer preburner augmented spark igniter purge check valve not being fully closed due to contamination. The source of the contaminant was traced to a cut segment from a rubber O-ring which was used in a fine clean tool during valve production prior to 1992. The valve was apparently contaminated during its fabrication in 1985. The valve had performed acceptably on four previous flights of the engine, and SSME flight history shows 780 combined check valve flights without failure. The failure of an Engine 3 (SSME No. 2011) check valve to close was sensed by onboard engine instruments even though all other engine operations were normal. This resulted in an engine shutdown and safe sequential shutdown of all three engines prior to ignition of the solid boosters. Derived from text

RESULTS OF EXPERIMENTAL INVESTIGATIONS TO DETERMINE EXTERNAL TANK PROTUBERANCE LOADS USING A 0.03-SCALE MODEL OF THE SPACE SHUTTLE LAUNCH CONFIGURATION (MODEL 47-OTS) IN THE NASA/ARC UNITARY PLAN WIND TUNNEL, VOLUME 1

S. R. Houlihan (Rockwell International Corp., Los Angeles, CA.) Feb. 1992 414 p

(Contract NAS9-17840)

(NASA-CR-167690; NAS 1.26:167690; DMS-DR-2476-Vol-1) Avail: CASI HC A18/MF A04

Data were obtained on a 3-percent model of the Space Shuttle launch vehicle in the NASA/Ames Research Center 11x11-foot and 9x7-foot Unitary Plan Wind Tunnels. This test series has been identified as IA190A/B and was conducted from 7 Feb. 1980 to 19 Feb. 1980 (IA190A) and from 17 March 1980 to 19 March 1980 and from 8 May 1980 to 30 May 1980 (IA190B). The primary test objective was to obtain structural loads on the following external tank protuberances: (1) LO2 feedline, (2) GO2 pressure line, (3) LO2 antigeyser line, (4) GH2 pressure line, (5) LH2 tank cable tray, (6) LO2 tank cable tray, (7) Bipod, (8) ET/SRB cable tray, and (9) Crossbeam/Orbiter cable tray. To fulfill these objectives the following steps were taken: (1) Eight 3-component balances were used to measure forces on various sections of 1 thru 6 above. (2) 315 pressure orifices were distributed over all 9 above items. The LO2 feedline was instrumented with 96 pressure taps and was rotated to four positions to yield 384 pressure measurements. The LO2 antigeyser line was instrumented with 64 pressure taps and was rotated to two positions to yield 128 pressure measurements. (3) Three Chrysler miniature flow direction probes were mounted on a traversing mechanism on the tank upper surface centerline to obtain flow field data between the forward and aft attach structures. (4) Schlieren photographs and ultraviolet flow photographs were taken at all test conditions. Data from each of the four test phases are presented.

PROCEDURES FOR ANALYSIS OF DEBRIS RELATIVE TO SPACE SHUTTLE SYSTEMS Final Report, Jan. 1992 - Jul. 1993

Hae Soo Kim and Virginia J. Cummings May 1993 88 p Original contains color illustrations

(NASA-TM-109190; NAS 1.15:109190) Avail: CASI HC A05/MF A01; 8 functional color pages

Debris samples collected from various Space Shuttle systems have been submitted to the Microchemical Analysis Branch. This investigation was initiated to develop optimal techniques for the analysis of debris. Optical microscopy provides information about the morphology and size of crystallites, particle sizes, amorphous phases, glass phases, and poorly crystallized materials. Scanning electron microscopy with energy dispersive spectrometry is utilized for information on surface morphology and qualitative elemental content of debris. Analytical electron microscopy with wavelength dispersive spectrometry provides information on the quantitative elemental content of debris.

RESULTS OF WIND TUNNEL TESTS OF AN ASRM CONFIGURED 0.03 SCALE SPACE SHUTTLE INTEGRATED VEHICLE MODEL (47-OTS) IN THE AEDC 16-FOOT TRANSONIC WIND TUNNEL, VOLUME 2

J. Marroquin (Rockwell International Corp., Downey, CA.) and P. Lemoine (Rockwell International Corp., Downey, CA.) Oct. 1992 393 p Microfiche as supplement

(Contract NAS9-17840)

(NASA-CR-185697; NAS 1.26:185697; DMS-DR-2549-Vol-2) Avail: CASI HC A17/MF A04

An experimental Aerodynamic and Aero-Acoustic loads data base was obtained at transonic Mach numbers for the Space Shuttle Launch Vehicle configured with the ASRM Solid Rocket Boosters as an increment to the current flight configuration (RSRB). These data were obtained during transonic wind tunnel tests (IA 613A) conducted in the Arnold Engineering Development Center 16-Foot transonic propulsion wind tunnel from March 27, 1991 through April 12, 1991. This test is the first of a series of two tests covering the Mach range from 0.6 to 3.5. Steady state surface static and fluctuating pressure distributions over the Orbiter, External Tank and Solid Rocket Boosters of the Shuttle Integrated Vehicle were measured. Total Orbiter forces, Wing forces and Elevon hinge moments were directly measured as well from force balances. Two configurations of Solid Rocket Boosters were tested, the Redesigned Solid Rocket Booster (RSRB) and the Advanced Solid Rocket Motor (ASRM). The effects of the position (i.e., top, bottom, top and bottom) of the Integrated Electronics Assembly (IEA) box, mounted on the SRB attach ring, were obtained on the ASRM configured model. These data were obtained with and without Solid Plume Simulators which, when used, matched as close as possible the flight derived pressures on the Orbiter and External Tank base. Data were obtained at Mach numbers ranging from 0.6 to 1.55 at a Unit Reynolds Number of 2.5 million per foot through model angles of attack from -8 to +4 degrees at sideslip angles of 0, +4 and -4 degrees.

TROPIX: A SOLAR ELECTRIC PROPULSION FLIGHT EXPERIMENT

J. Mark Hickman, G. Barry Hillard, and Steven R. Oleson (Sverdrup Technology, Inc., Brook Park, OH.) Sep. 1993 10 p Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA, AIDAA, DGLR, and JSASS

(RTOP 920-20-08)

(NASA-TM-106297; E-8035; NAS 1.15:106297; IEPC-93-063) Avail: CASI HC A02/MF A01

The Transfer Orbit Plasma Interaction Experiment (TROPIX) is a proposed scientific experiment and flight demonstration of a solar electric propulsion vehicle. Its mission goals are to significantly increase our knowledge of Earth's magnetosphere and its associated plasma environment and to demonstrate an operational solar electric upper stage (SEUS) for small launch vehicles. The scientific investigations and flight demonstration technology experiments are uniquely interrelated because of the spacecraft's interaction with the surrounding environment. The data obtained will complement previous studies of the Earth's magnetosphere and space plasma environment by supplying the knowledge necessary to attain the strategic objectives of the NASA Office of Space Science. This first operational use of a primary ion propulsion vehicle, designed to withstand the harsh environments from low Earth orbit to geosynchronous Earth orbit, may lead to the development of a new class of electric propulsion upper stages or space-based transfer vehicles and may improve future spacecraft design and safety.

A study on the system design and the technical problems of the HOPE (H-2 Orbiting Plane) subsystem, especially on tip fin feasibility study and trade-off of orbit injection system and major structural materials which is deemed to have great effects on establishing basic specifications of the airframe are conducted based on the results of studies conducted till last year. Reflecting the results of the above studies, the HOPE system study, study of overall operation concept, overall operation system and impact ellipse area, and development program were conducted. The items concerning the feasibility of the HOPE system was made clear and the accuracy of the study on those points was improved. Problems such as the lack of design data which is important for basic configuration establishment were pointed out, and the design theories were made clear. Author (NASDA)

STS-53 SPACE SHUTTLE MISSION REPORT
Robert W. Fricke, Jr. Feb. 1993 39 p Sponsored by NASA. Johnson Space Center
(NASA-CR-193101; NAS 1.26:193101; NSTS-08281) Avail: CASI HC A03/MF A01

The STS-53 Space Shuttle Program Mission Report provides a summary of the Orbiter, External Tank (ET), Solid Rocket Booster/Redesigned Solid Rocket Motor (SRB/RSRM), and the Space Shuttle Main Engine (SSME) subsystems performance during the fifty-second flight of the Space Shuttle Program, and the fifteenth flight of the Orbiter vehicle Discovery (OV-103). In addition to the Orbiter, the flight vehicle consisted of an ET, which was designated as ET-49/LWT-42; three SSME's, which were serial numbers 2024, 2012, and 2017 in positions 1, 2, and 3, respectively; and two SRB's, which were designated BI-055. The lightweight RSRM's that were installed in each SRB were designated 360L028A for the left SRB, and 360L028B for the right SRB. The primary objective of this flight was to successfully deploy the Department of Defense 1 (DOD-1) payload. The secondary objectives of this flight were to perform the operations required by the Glow Experiment/Cryogenic Heat Pipe Experiment Payload (GCP); the Hand-Held, Earth-Oriented, Real-Time, Cooperative, User-Friendly, Location-Targeting and Environmental System (HERCULES); the Space Tissue Loss (STL); the Battlefield Laser Acquisition Sensor Test (BLAST); the Radiation Monitoring Equipment-III (RME-III); the Microcapsules in Space-1 (MIS-1); the Visual Function Tester-2 (VFT-2); the Cosmic Radiation Effects and Activation Monitor (CREAM); the Clouds Logic to Optimize Use of Defense Systems-1A (CLOUDS-1A); the Fluids Acquisition and Resupply Experiment (FARE); and the Orbital Debris Radar Calibration Spheres (ODERACS). In addition to presenting a summary of subsystem performance, this report also discusses each Orbiter, ET, SSME, SRB, and RSRM in-flight anomaly in the applicable section of the report. Listed in the discussion of each anomaly is the officially assigned tracking number as published by each Project Office in their respective Problem Tracking List. All times given in this report are in Greenwich mean time (G.m.t.) as well as mission elapsed time (MET). Author (revised)

The STS-54 Space Shuttle Program Mission Report is a summary of the Orbiter, External Tank (ET), Solid Rocket Booster/Redesigned Solid Rocket Motor (SRB/RSRM), and the Space Shuttle Main Engine (SSME) subsystems performance during this fifty-third flight of the Space Shuttle Program, and the third flight of the Orbiter vehicle Endeavour (OV-105). In addition to the Orbiter, the flight vehicle consisted of an ET, which was designated ET-51; three SSME's, which were serial numbers 2019, 2033, and 2018 in positions 1, 2, and 3, respectively; and two retrievable and reusable SRB's which were designated BI-056. The lightweight RSRM's that were installed in each SRB were designated 360L029A for the left SRB, and 360L029B for the right SRB. The primary objectives of this flight were to perform the operations to deploy the Tracking and Data Relay Satellite-F/Inertial Upper Stage payload and to fulfill the requirements of the Diffuse X-Ray Spectrometer (DXS) payload. The secondary objective was to fly the Chromosome and Plant Cell Division in Space (CHROMEX), Commercial Generic Bioprocessing Apparatus (CGBA), Physiological and Anatomical Rodent Experiment (PARE), and the Solid Surface Combustion Experiment (SSCE). In addition to presenting a summary of subsystem performance, this report also discusses each Orbiter, ET, SSME, SRB, and RSRM in-flight anomaly in the applicable section of the report. The official tracking number for each in-flight anomaly, assigned by the cognizant project, is also shown. All times are given in Greenwich mean time (G.m.t.) and mission elapsed time (MET). RESULTS OF EXPERIMENTAL INVESTIGATIONS TO DETERMINE EXTERNAL TANK PROTUBERANCE LOADS USING A 0.03-SCALE MODEL OF THE SPACE SHUTTLE LAUNCH CONFIGURATION (MODEL 47-OTS) IN THE NASA/ARC UNITARY PLAN WIND TUNNEL, VOLUME 2

S. R. Houlihan (Rockwell International Corp., Los Angeles, CA.) Feb. 1992 80 p Microfiche as supplement
(Contract NAS9-17840)
(NASA-CR-167691; NAS 1.26:167691; DMS-DR-2476-Vol-2) Avail: CASI HC A05/MF A01

Data were obtained on a 3-percent model of the Space Shuttle launch vehicle in the NASA/Ames Research Center 11x11-foot and 9x7-foot Unitary Plan Wind Tunnels. This test series has been identified as IA19OA/B and was conducted from 7 Feb. 1980 to 19 Feb. 1980 (IA19OA) and from 17 March 1980 to 19 March 1980 and from 8 May 1980 to 30 May 1980 (IA19OB). The primary test objective was to obtain structural loads on the following external tank protuberances: (1) LO2 feedline; (2) GO2 pressure line; (3) LO2 antigeyser line; (4) GH2 pressure line; (5) LH2 tank cable tray; (6) LO2 tank cable tray; (7) Bipod; (8) ET/SRB cable tray; and (9) Crossbeam/Orbiter cable tray. To fulfill these objectives the following steps were taken: Eight 3-component balances were used to measure forces on various sections of 1 thru 6 above; 315 pressure orifices were distributed over all 9 above items. The LO2 feedline was instrumented with 96 pressure taps and was rotated to four positions to yield 384 pressure measurements. The LO2 antigeyser line was instrumented with 64 pressure taps and was rotated to two positions to yield 128 pressure measurements; Three Chrysler miniature flow direction probes were mounted on a traversing mechanism on the tank upper surface centerline to obtain flow field data between the forward and aft attach structures; and Schlieren photographs and ultraviolet flow photographs were taken at all test conditions. Data from each of the four test phases are presented. Author

THE CONCEPTUAL STUDY ON FUTURE SPACE TRANSPORTATION SYSTEMS. PART A: CONCEPTUAL STUDY OF FLYBACK BOOSTER [SHOURAIGATA ROKETTO NO KENKYUU: FURAIBAKKU BASUTA NO GAINEN KENTOU]

Tokyo, Japan National Space Development Agency 31 Mar. 1993 25 p
(NASDA-CNT-930013; JTN-93-80467) Avail: CASI HC A03/MF A01

The results of the study on a future space transportation system, a flyback booster, is presented. The initial sizing of the rocket was conducted, and the following guidelines concerning the selection of its configurations are presented: (1) the speed increment allotment for the booster is aimed at less than 3,000 m/s in an ideal velocity when the rocket is on the premise that the booster returning to the launch site; (2) to minimize the rocket size, upgrading the upper stage structural efficiency is effective in designing the flyback booster; and (3) assuming and comparing four kinds of returning systems, it is deemed most prosperous to return in ballistic flight by re-igniting the booster immediately after upper stage separation. A study was conducted on winged and flare type (non-winged) bodies as examples based on the initial sizing data, and it was concluded that both types are feasible within the category of the existing design and materials. THE CONCEPT STUDY OF THE SPACE TRANSPORTATION SYSTEM HOPE IN FY 1991 [HEISEI 3 NENDO HOPE GAINEN SEKKEI]

Tokyo, Japan National Space Development Agency 31 Mar. 1993 102 p
(NASDA-CNT-930016; JTN-93-80470) Avail: CASI HC A06/MF A02

An system design was conducted on the HOPE (H-2 Orbiting Plane), focusing on the following technical problems which are deemed to have great effects on the specifications of the airframe: (1) the feasibility of the tip fin; (2) trade-off of main airframe structure materials; and (3) trade-off of the orbit injection systems. The feasibility of HOPE was confirmed. The following items of the system and each subsystem were straightend up: (1) detail of the design requirements and their feasibility; (2) standard specifications of the airframe and its alternatives; and (3) design studies. In a development concept study, it was confirmed that the HOPE first launch in FY (Fiscal Year) 2000 will be possible by advancing the development systematically. Author (NASDA)

AN INTEGRATED KNOWLEDGE SYSTEM FOR THE SPACE SHUTTLE HAZARDOUS GAS DETECTION SYSTEM Final Report, Jun. 1990 - Sep. 1993

Ching F. Lo, George Z. Shi, Carl Bangasser, Connie Fensky, Eric Cegielski, and Glenn Overbey 7 Oct. 1993 17 p
(Grant NAG8-835)
(NASA-CR-194533; NAS 1.26:194533) Avail: CASI HC A03/MF A01

A computer-based integrated Knowledge-Based System, the Intelligent Hypertext Manual (IHM), was developed for the Space Shuttle Hazardous Gas Detection System (HGDS) at NASA Marshall Space Flight Center (MSFC). The IHM stores HGDS related knowledge and presents it in an interactive and intuitive manner. This manual is a combination of hypertext and an expert system which store experts' knowledge and experience in hazardous gas detection and analysis. The IHM's purpose is to provide HGDS personnel with the capabilities of: locating applicable documentation related to procedures, constraints, and previous fault histories; assisting in the training of personnel; enhancing the interpretation of real time data; and recognizing and identifying possible faults in the Space Shuttle sub-systems related to hazardous gas detection. THE DEVELOPMENT AND FLIGHT TEST OF A DEPLOYABLE PRECISION LANDING SYSTEM FOR SPACECRAFT RECOVERY
Alex G. Sim, James E. Murray, David C. Neufeld, and R. Dale Reed (PRC Kentron, Inc., Edwards, CA.) Sep. 1993 31 p
(RTOP 505-68-50)
(NASA-TM-4525; H-1933; NAS 1.15:4525) Avail: CASI HC A03/MF A01

A joint NASA Dryden Flight Research Facility and Johnson Space Center program was conducted to determine the feasibility of the autonomous recovery of a spacecraft using a ram-air parafoil system for the final stages of entry from space that included a precision landing. The feasibility of this system was studied using a flight model of a spacecraft in the generic shape of a flattened biconic which weighed approximately 150 lb and was flown under a commercially available, ram-air parachute. Key elements of the vehicle included the Global Positioning System guidance for navigation, flight control computer, ultrasonic sensing for terminal altitude, electronic compass, and onboard data recording. A flight test program was used to develop and refine the vehicle. This vehicle completed an autonomous flight from an altitude of 10,000 ft and a lateral offset of 1.7 miles which resulted in a precision flare and landing into the wind at a predetermined location. At times, the autonomous flight was conducted in the presence of winds approximately equal to vehicle airspeed. Several techniques for computing the winds postflight were evaluated. Future program objectives are also presented. Author (revised)

Alternatives for realizing a packet-based network switch for use on a frequency division multiple access/time division multiplexed (FDMA/TDM) geostationary communication satellite were investigated. Each of the eight downlink beams supports eight directed dwells. The design needed to accommodate multicast packets with very low probability of loss due to contention. Three switch architectures were designed and analyzed. An output-queued, shared bus system yielded a functionally simple system, utilizing a first-in, first-out (FIFO) memory per downlink dwell, but at the expense of a large total memory requirement. A shared memory architecture offered the most efficiency in memory requirements, requiring about half the memory of the shared bus design. The processing requirement for the shared-memory system adds system complexity that may offset the benefits of the smaller memory. An alternative design using a shared memory buffer per downlink beam decreases circuit complexity through a distributed design, and requires at most 1000 packets of memory more than the completely shared memory design. Modifications to the basic packet switch designs were proposed to accommodate circuit-switched traffic, which must be served on a periodic basis with minimal delay. Methods for dynamically controlling the downlink dwell lengths were developed and analyzed. These methods adapt quickly to changing traffic demands, and do not add significant complexity or cost to the satellite and ground station designs. Methods for reducing the memory requirement by not requiring the satellite to store full packets were also proposed and analyzed. In addition, optimal

packet and dwell lengths were computed as functions of memory size for the three switch architectures. Author (revised)

(NASA-TP-3379; E-7635; NAS 1.60:3379) Avail: CASI HC A03/MF A01

A major goal of the Digital Systems Technology Branch at the NASA Lewis Research Center is to identify and develop critical digital components and technologies that either enable new commercial missions or significantly enhance the performance, cost efficiency, and/or reliability of existing and planned space communications systems. NASA envisions a need for low-data-rate, interactive, direct-to-the-user communications services for data, voice, facsimile, and video conferencing. The network would provide enhanced very-small-aperture terminal (VSAT) communications services and be capable of handling data rates of 64 kbps through 2.048 Mbps in 64-kbps increments. Efforts have concentrated heavily on the space segment; however, the ground segment has been considered concurrently to ensure cost efficiency and realistic operational constraints. The focus of current space segment developments is a flexible, high-throughput, fault-tolerant onboard information-switching processor (ISP) for a geostationary satellite communications network. The Digital Systems Technology Branch is investigating both circuit and packet architectures for the ISP. Destination-directed, packet-switched architectures for geostationary communications satellites are addressed. Author (revised)

THERMAL EXPERT SYSTEM (TEXSYS): SYSTEMS AUTOMONY DEMONSTRATION PROJECT, VOLUME 1. OVERVIEW Final Report

B. J. Glass, ed. Oct. 1992 22 p

(RTOP 549-03-11)

(NASA-TM-102877; A-90319-Vol-1; NAS 1.26:102877) Avail: CASI HC A03/MF A01

The Systems Autonomy Demonstration Project (SADP) produced a knowledge-based real-time control system for control and fault detection, isolation, and recovery (FDIR) of a prototype two-phase Space Station Freedom external active thermal control system (EATCS). The Thermal Expert System (TEXSYS) was demonstrated in recent tests to be capable of reliable fault anticipation and detection, as well as ordinary control of the thermal bus. Performance requirements were addressed by adopting a hierarchical symbolic control approach-layering model-based expert system software on a conventional, numerical data acquisition and control system. The model-based reasoning capabilities of TEXSYS were shown to be advantageous over typical rule-based expert systems, particularly for detection of unforeseen faults and sensor failures. Volume 1 gives a project overview and testing highlights. Volume 2 provides detail on the EATCS test bed, test operations, and online test results. Appendix A is a test archive, while Appendix B is a compendium of design and user manuals for the TEXSYS software. Author (revised)

APPLICATION OF NEW ELECTRO-OPTIC TECHNOLOGY TO SPACE STATION FREEDOM DATA MANAGEMENT SYSTEM

C. R. Husbands and M. M. Girard Aug. 1993 75 p

(Contract NASw-4358)

(NASA-CR-177622; A-93117; NAS 1.26:177622) Avail: CASI HC A04/MF A01

A low risk design methodology to permit the local bus structures to support increased data carrying capacities and to speed messages and data flow between nodes or stations on the Space Station Freedom Data Management System in anticipation of growing requirements was evaluated and recommended. The recommended design employs a collateral fiber optic technique that follows a NATO avionic standard that is developed, tested, and available. Application of this process will permit a potential 25 fold increase in data transfer performance on the local wire bus network with a fiber optic network, maintaining the functionality of the low-speed bus and supporting all of the redundant transmission and fault detection capabilities designed into the existing system. The application of wavelength division multiplexing (WDM) technology to both the local data bus and global data bus segments of the Data Management System to support anticipated additional highspeed data transmission requirements was also examined. Techniques were examined to provide a dual wavelength implementation of the fiber optic collateral networks. This dual wavelength implementation would permit each local bus to support two simultaneous high-speed transfers on the same fiber optic bus structure and operate within the limits of the existing protocol standard. A second WDM study examined the use of spectral sliced technology to provide a fourfold increase in the Fiber Distributed Data Interface (FDDI) global bus networks without requiring modifications to the existing installed cable plant. Computer simulations presented indicated that this data rate improvement can be achieved with commercially available optical components. Author (revised)

SCAILET: AN INTELLIGENT ASSISTANT FOR SATELLITE GROUND TERMINAL OPERATIONS

A. K. Shahidi, J. A. Crapo, R. F. Schlegelmilch, R. C. Reinhart (Analex Corp., Brook Park, OH.), E. J. Petrik, J. L. Walters, and R. E. Jones May 1993 10 p Presented at the World Space Congress, Washington, DC, 28 Aug. - 5 Sep. 1993; sponsored by NASA, AIAA, and NAS Previously announced in IAA as A92-55855

(RTOP 506-72-1D)

(NASA-TM-105879; E-7302; NAS 1.15:105879) Avail: CASI HC A02/MF A01

NASA Lewis Research Center has applied artificial intelligence to an advanced ground terminal. This software application is being deployed as an experimenter interface to the link evaluation terminal (LET) and was named Space Communication Artificial Intelligence for the Link Evaluation Terminal (SCAILET). The high-burst-rate (HBR) LET provides 30-GHz-transmitting and 20-GHz-receiving, 220-Mbps capability for wide band communications technology experiments with the Advanced Communication Technology Satellite (ACTS). The HBR-LET terminal consists of seven major subsystems. A minicomputer controls and monitors these subsystems through an IEEE-488 or RS-232 protocol interface. Programming scripts (test procedures defined by design engineers) configure the HBR-LET and permit data acquisition. However, the scripts are difficult to use, require a steep learning curve, are cryptic, and are hard to maintain. This discourages experimenters from utilizing the full capabilities of the HBR-LET system. An intelligent assistant module was developed as part of the SCAILET software. The intelligent assistant addresses critical experimenter needs by solving and resolving problems that are encountered during the configuring of the HBR-LET system. The intelligent assistant is a graphical user interface with an expert system running in the background. In order to further assist and familiarize an experimenter, an on-line hypertext documentation module was developed and included in the SCAILET software. Author (revised)

NONLINEAR DAMPING MODEL FOR FLEXIBLE STRUCTURES Ph.D. Thesis

Weijian Zang Dec. 1990 178 p Sponsored by NASA. Dryden Flight Center

(Grant NsG-4015)

(NASA-CR-193711; NAS 1.26:193711; TR-1-FSRL-1990) Avail: CASI HC A09/MF A02

The study of nonlinear damping problem of flexible structures is addressed. Both passive and active damping, both finite dimensional and infinite dimensional models are studied. In the first part, the spectral density and the correlation function of a single DOF nonlinear damping model is investigated. A formula for the spectral density is established with O(Gamma(sub 2)) accuracy based upon Fokker-Planck technique and perturbation. The spectral density depends upon certain first order statistics which could be obtained if the stationary density is known. A method is proposed to find the approximate stationary density explicitly. In the second part, the spectral density of a multi-DOF nonlinear damping model is investigated. In the third part, energy type nonlinear damping model in an infinite dimensional setting is studied. Author (revised)

CFM TECHNOLOGIES FOR SPACE TRANSPORTATION: MULTIPURPOSE HYDROGEN TESTBED SYSTEM DEFINITION AND TANK PROCUREMENT Final Report

E. C. Fox, E. R. Kiefel, G. L. McIntosh, J. B. Sharpe, D. R. Sheahan, and M. E. Wakefield Jul. 1993 93 p

(Contract NAS8-39201)

(NASA-CR-194355; NAS 1.26:194355) Avail: CASI HC A05/MF A01

The development of a test bed tank and system for evaluating cryogenic fluid management technologies in a simulated upper stage liquid hydrogen tank is covered. The tank is 10 ft long and is 10 ft in diameter, and is an ASME certified tank constructed of 5083 aluminum. The tank is insulated with a combination of sprayed on foam insulation, covered by 45 layers of double aluminized mylar separated by dacron net. The mylar is applied by a continuous wrap system adapted from commercial applications, and incorporates variable spacing between the mylar to provide more space between those layers having a high delta temperature, which minimizes heat leak. It also incorporates a unique venting system which uses fewer large holes in the mylar rather than the multitude of small holes used conventionally. This significantly reduces radiation heat transfer. The test bed consists of an existing vacuum chamber at MSFC, the test bed tank and its thermal control system, and a thermal shroud (which may be heated) surrounding the tank. Provisions are made in the tank and chamber for inclusion of a variety of cryogenic fluid management experiments. Author (revised)

EXPERIMENTAL TECHNIQUE TO SIMULATE ORBITAL-DEBRIS IMPACT ON SPACE SHIELDS AT IMPACT VELOCITIES OVER 10 km/s

L. C. Chhabildas and M. B. Boslough 1992 5 p Presented at the First European Conference on Space Debris, Darmstadt, Germany, 5-8 Apr. 1993

(Contract DE-AC04-76DP-00789)

(DE93-011619; SAND-92-2460C; CONF-9304135-1) Avail: CASI HC A01/MF A01

With the development of a new HyperVelocity Launcher, HVL, at Sandia, it is now possible to perform experiments over the velocity range of 7 to 12 km/s. This velocity range has not been previously accessible for gram-size plates. This meets the requisite mass-velocity criteria established for the orbital debris environment. In this paper, the technique employed to launch thin flier plates to velocities not previously accessible on a two-stage light-gas gun is reported. In particular, this technique has been used on a two-stage light-gas gun to launch nominally 0.5 to 1.0-mm thick aluminum, titanium, and magnesium flier plates intact to velocities up to 12.2 km/s. Since the mass-velocity capability of the newly developed HVL meets the average specifications of the space debris environment, it is expected to be a useful tool to evaluate the effects of debris impact on space structures and debris shields. Examples of a plate impact i.e., orbital debris impact on a thin Whipple shield are presented in this paper. DOE

AN EXPERIMENTAL STUDY OF TETHER REEL SYSTEM: A LABORATORY MODEL

Shoichi Yoshimura and Osamu Okamoto Aug. 1992 18 p In ENGLISH and JAPANESE

(NAL-TR-1176T; JTN-93-80495) Avail: CASI HC A03/MF A01

A laboratory prototype model of a reel system has been made as the first step of an in-house hardware study of the tether system in space. The model consists of two main parts: a Reel Drum Driving (RDD) unit (25 kg weight) and a Power Supply/Signal Processing (PSSP) unit (32 kg). The tether (0.8 mm in diameter and 300 m long) consists of a Kevlar fiber core and a nylon fiber jacket. Following the preliminary functional test, a computer-controlled functional test has been carried out using a 32-bit personal computer as a control processor. The tests have shown that the stable operations of reel-out and reel-in are possible by tension control in both cases of a small tension (light end weight) and a high frequency input to the reel drum driving motor. SYSTEM IDENTIFICATION FOR SPACE STATION FREEDOM USING OBSERVER/KALMAN FILTER MARKOV PARAMETERS M.S. Thesis

Michael Papadopoulos and Robert H. Tolson Aug. 1993 122 p

(Grant NAG1-1416; RTOP 590-14-31-01)

(NASA-CR-191521; NAS 1.26:191521) Avail: CASI HC A06/MF A02

The Modal Identification Experiment (MIE) is a proposed experiment to define the dynamic characteristics of Space Station Freedom. Previous studies emphasized free-decay modal identification. The feasibility of using a forced response method (Observer/Kalman Filter Identification (OKID)) is addressed. The interest in using OKID is to determine the input mode shape matrix which can be used for controller design or control-structure interaction analysis, and investigate if forced response methods may aid in separating closely spaced modes. A model of the SC-7 configuration of Space Station Freedom was excited using simulated control system thrusters to obtain acceleration output. It is shown that an 'optimum' number of outputs exists for OKID. To recover global mode shapes, a modified method called Global-Local OKID was developed. This study shows that using data from a long forced response followed by free-decay leads to the 'best' modal identification. Twelve out of the thirteen target modes were identified for such an output. Author (revised)

COMPARISON OF ANALYTIC WHIPPLE BUMPER SHIELD BALLISTIC LIMITS WITH CTH SIMULATIONS

E. S. Hertel, Jr. May 1993 64 p

(Contract DE-AC04-76DP-00789)

(DE93-015126; SAND-92-0347) Avail: CASI HC A04/MF A01

A series of CTH simulations were conducted to assess the feasibility of using the hydrodynamic code for debris cloud formation and to predict any damage due to the subsequent loading on rear structures. Six axisymmetric simulations and one 3-dimensional simulation were conducted

for spherical projectiles impacting Whipple bumper shields. The projectile diameters were chosen to correlate with two well known analytic expressions for the ballistic limit of a Whipple bumper shield. It has been demonstrated that CTH can be used to simulate the debris cloud formation, the propagation of the debris across a void region, and the secondary impact of the debris against a structure. In addition, the results from the CTH simulations were compared to the analytic estimates of the ballistic limit. At impact velocities of 10 km/s or less, the CTH predicted ballistic limit lays between the two analytic estimates. However, for impact velocities greater than 10 km/s, CTH simulations predicted a ballistic limit larger than both analytical estimates. The differences at high velocities are not well understood. Structural failure at late times due to the time integrated loading of a very diffuse debris cloud has not been considered in the CTH model. In addition, the analytic predictions are extrapolated from relatively low velocity data and the extrapolation technique may not be valid. The discrepancy between the two techniques should be investigated further. DOE

FEASIBILITY STUDY OF AN ORBITING LABORATORY FOR TESTING CSI TECHNOLOGY Final Report
Andrew S. Bicos and Gregory G. Loboda Aug. 1993 108 p
(Contract NAS1-18763; RTOP 585-03-11-08)
(NASA-CR-191524; NAS 1.26:191524; MDC-93H0100) Avail: CASI HC A06/MF A02

A concept for an orbiting laboratory for testing Controls-Structures Integration (CSI) technology is described. The CSI-Star concept reflects a lower cost, higher risk approach. The concept supports demonstration and validation testing for critical CSI technologies at a cost of $20M to $26M with a 1-year reliability of approximately 0.9. The Ball Aerospace QuickStar bus is the carrier for the CSI test article. QuickStar is launched as a secondary payload on the McDonnell Douglas Delta 2. The QuickStar/Delta 2 approach is flight proven. The CSI test article is a 20 foot, 1 Hz, truss beam which is deployed from the QuickStar bus. The test article is well instrumented for quality system identification. The laboratory provides three layers of active control consisting of global vibration suppression along the truss beam, vibration isolation between the beam and instrument platforms, and vibration compensation through the use of gimbaled platforms which point lasers relative to optical sensor targets. The configuration simulates the dynamics of multi-instrument science platforms such as those of the Earth Observation System (EOS) while maintaining strong ties to astrophysics missions such as the Optical Interferometer. Uplink/downlink services and a reprogrammable computer provide flexibility for long-term investigations by members of the CSI community (NASA, DoD, academia, and industry). CSI-Star fills the gap between short-term experiments, which have been conducted primarily on the Shuttle, and future science missions which require the technology. The on-orbit maturity of CSI technology must be established to obtain acceptance by project managers and to promote injection of the technology into future science missions. Author (revised)

PHOBOS/HARP POST LAUNCH SUPPORT Final Technical Report, May 1993
Andrew Nagy 25 Jun. 1993 3 p
(Grant NAGw-631)
(NASA-CR-193676; NAS 1.26:193676) Avail: CASI HC A01/MF A01

The activity under this grant concentrated on: (1) post-launch calibration of the HARP instrument; and (2) analysis and interpretation of the data from the HARP and other related instruments. The HARP was taken by scientists and engineers from the Hungarian Central Research Institute for Physics (CRIP) to NASA/MSFC for calibration in their plasma chamber, with partial support of this grant. This electron and ion calibration of the HARP, helped in transforming measured currents to actual flux values. The analysis and interpretation of the data, carried out jointly by our Russian and Hungarian colleagues and us, led to a number of journal publications and presentations at scientific meetings. DYNAMICS OF ADAPTIVE STRUCTURES: DESIGN THROUGH SIMULATIONS
K. C. Park and S. Alexander 1993 5 p
(Grant NAG9-574)
(NASA-CR-193724; NAS 1.26:193724) Avail: CASI HC A01/MF A01

The use of a helical bi-morph actuator/sensor concept by mimicking the change of helical waveform in bacterial flagella is perhaps the first application of bacterial motions (living species) to longitudinal deployment of space structures. However, no dynamical considerations were analyzed to explain the waveform change mechanisms. The objective is to review various deployment concepts from the dynamics point of view and introduce the dynamical considerations from the outset as part of design considerations. Specifically, the impact of the incorporation of the combined static mechanisms and dynamic design considerations on the deployment performance during the reconfiguration stage is studied in terms of improved controllability, maneuvering duration, and joint singularity index. It is shown that intermediate configurations during articulations play an important role for improved joint mechanisms design and overall structural deployability. Derived from text

LOW COST ATTITUDE CONTROL SYSTEM REACTION WHEEL DEVELOPMENT Final Report
William Bialke 8 Mar. 1991 100 p
(Contract NAS5-30307; SBIR-09.20-7640)
(NASA-CR-191332; NAS 1.26:191332; Rept-94044) Avail: CASI HC A06/MF A02

In order to satisfy a growing demand for low cost attitude control systems for small spacecraft, development of a low power and low cost Reaction Wheel Assembly was initiated. The details of the versatile design resulting from this effort are addressed. Tradeoff analyses for each of the major components are included, as well as test data from an engineering prototype of the hardware. Author (revised)

TRANSMISSION ZEROS OF SPACECRAFT ATTITUDE CONTROL SYSTEM [JINKOU EISEI SHISEI SEIGYOKEI NO DENTATSU ZERO]
Takashi Kida and Isao Yamaguchi Jun. 1992 17 p In JAPANESE
(NAL-TR-1166; JTN-93-80486) Avail: CASI HC A03/MF A01

The importance of evaluating the control performance and the robust stability in the frequency-domain is being widely recognized. A pair of poles and zeros is a candidate characterizing the model of the control system when it is described in the transfer matrix form. This paper studies poles and zeros of a multi-input/multi-output spacecraft attitude control system. Some algebraic algorithms for obtaining them are derived, and their dynamical properties are clarified. The transmission zero, among many definitions of the multi-variable zeros, is considered. SIMULATION OF ORBITAL DEBRIS IMPACTS ON BUMPER SHIELDS
E. S. Hertel, Jr. 1992 6 p Presented at the 1st European Conference on Space Debris, Darmstadt, Germany, 5-8 Apr. 1993
(Contract DE-AC04-76DP-00789)
(DE93-013773; SAND-92-2090C; CONF-9304135-2) Avail: CASI HC A02/MF A01

A series of numerical simulations were performed using CTH to predict secondary debris formation and rear structure damage for typical bumper shields under a variety of impact geometries The simulations span a range of velocities from approximately 3 to 12 km/s and are compared to the experiment data for the lower velocities (3 to 7 km/s). For one velocity (approximately 7 km/s), CTH was used to demonstrate the effects of bumper thickness on secondary debris formation and rear structure damage. CTH was also used to stimulate a 12 km/s impact of a sphere on a simple Whipple bumper shield, and this result will be compared to analytic damage predictions at that velocity. It has been found that CTH accurately predicts secondary debris propagation and rear damage for velocities throughout the experimentally accessible range. The CTH damage predictions at 12 km/s result in a higher ballistic limit than would be predicted from the analytic techniques. DOE

Avail: CASI HC A03/MF A01

Spacecraft inevitably interact with their environments. Besides the interactions one immediately thinks of in space (zero-g, solar heating, atmospheric drag, expansion into vacuum conditions, etc.) other interactions are also important. Those of interest to spacecraft designers so far may be grouped under several headings; plasma interactions and spacecraft charging, impact of debris and micrometeoroids, chemical reactions with neutral species, radiation degradation, etc. Researchers have made great progress in defining and evaluating the interactions of spacecraft with their expected ambient environments near Earth and in interplanetary space. Some of these interactions are discussed with an eye toward expanding our knowledge into new environments, such as may be found at the moon and Mars, that will interact in new and different ways with exploring spacecraft and spacefarers. TECHNIQUES FOR ESTIMATING SPACE STATION AERODYNAMIC CHARACTERISTICS Final Technical Report, 1 Jul. 1989 - 31 Aug. 1992
Richard E. Thomas 1993 85 p
(Grant NAG9-386)
(NASA-CR-193394; NAS 1.26:193394) Avail: CASI HC A05/MF A01

A method was devised and calculations were performed to determine the effects of reflected molecules on the aerodynamic force and moment coefficients for a body in free molecule flow. A procedure was developed for determining the velocity and temperature distributions of molecules reflected from a surface of arbitrary momentum and energy accommodation. A system of equations, based on momentum and energy balances for the surface, incident, and reflected molecules, was solved by a numerical optimization technique. The minimization of a 'cost' function, developed from the set of equations, resulted in the determination of the defining properties of the flow reflected from the arbitrary surface. The properties used to define both the incident and reflected flows were: average temperature of the molecules in the flow, angle of the flow with respect to a vector normal to the surface, and the molecular speed ratio. The properties of the reflected flow were used to calculate the contribution of multiply reflected molecules to the force and moments on a test body in the flow. The test configuration consisted of two flat plates joined along one edge at a right angle to each other. When force and moment coefficients of this 90 deg concave wedge were compared to results that did not include multiple reflections, it was found that multiple reflections could nearly double lift and drag coefficients, with nearly a 50 percent increase in pitching moment for cases with specular or nearly specular accommodation. The cases of diffuse or nearly diffuse accommodation often had minor reductions

in axial and normal forces when multiple reflections were included. There were several cases of intermediate accommodation where the addition of multiple reflection effects more than tripled the lift coefficient over the convex technique. Author (revised)

ALFIS: ASTRONOMICAL LOW FREQUENCY INTERFEROMETRY SATELLITES. A FEASIBILITY STUDY

M. P. Nieuwenhuizen, Richard Beenen, ed., and Wim Simons, ed. Sep. 1992 214 p

(LR-699; ETN-93-94011) Copyright Avail: CASI HC A10/MF A03

Several aspects of the project concerning the Astronomical Low Frequency Interferometric Satellites (ALFIS) is discussed. These satellites are directed towards imaging the entire sky at frequencies below 15 mHz, which are inaccessible from the ground due to ionospheric absorption and scattering. This frequency range covers the lowest energy region of the electromagnetic spectrum that is essentially unexplored by astronomy. The ALFIS instrumental concept is a single launch bus which places two free flying spacecraft into almost identical geostationary transfer orbits with a small inclination between them to provide for baseline components at right angles to the orbital plane. ALFIS is less ambitious and cheaper than previous proposals submitted to NASA. ESA

(Contract NAS7-918)

(NASA-CR-194498; JPL-Publ-92-15-Vol-1; NAS 1.26:194498) Avail: CASI HC A11/MF A03

An improved methodology for quantitatively evaluating failure risk of spaceflight systems to assess flight readiness and identify risk control measures is presented. This methodology, called Probabilistic Failure Assessment (PFA), combines operating experience from tests and flights with engineering analysis to estimate failure risk. The PFA methodology is of particular value when information on which to base an assessment of failure risk, including test experience and knowledge of parameters used in engineering analyses of failure phenomena, is expensive or difficult to acquire. The PFA methodology is a prescribed statistical structure in which engineering analysis models that characterize failure phenomena are used conjointly with uncertainties about analysis parameters and/or modeling accuracy to estimate failure probability distributions for specific failure modes. These distributions can then be modified, by means of statistical procedures of the PFA methodology, to reflect any test or flight experience. Conventional engineering analysis models currently employed for design of failure prediction are used in this methodology. The PFA methodology is described and examples of its application are presented. Conventional approaches to failure risk evaluation for spaceflight systems are discussed, and the rationale for the approach taken in the PFA methodology is presented. The statistical methods, engineering models, and computer software used in fatigue failure mode applications are thoroughly documented. Author (revised)

LABORATORY SIMULATION OF SPACECRAFT CHARGING IN THE PLASMA WAKE REGION

Jan Troeim and Roe Eirik 25 Jan. 1993 41 p Original contains color illustrations

(Contract ESTEC-7989/88/NL/PB(SC))

(FFI-93-7007; ETN-93-94454) Avail: CASI HC A03/MF A01

An investigation as to how insulated areas on the wake side of a larger spacecraft model embedded in a streaming plasma are charged when being exposed to beams of fast electrons is presented. It is relevant to differential charging on satellites in orbits crossing polar latitudes where they may be subjected to high energy electron precipitation. The measurements are performed in a medium size vacuum system (1 m diameter by 2 m) with thermal plasma generator and an electron accelerator. The velocity of the plasma stream can be varied to simulate the relative speed of a spacecraft moving through the ionosphere. The electron accelerator can operate at energies corresponding to typical auroral electron energies. Results of charging of different materials (Kapton in particular) as a function of plasma density and electron energy are presented. It is demonstrated how a charged area on the wake side of the spacecraft model modifies the plasma density structure downstream on the wake side of the model. ESA

BALLIST: A COMPUTER PROGRAM TO EMPIRICALLY PREDICT THE BUMPER THICKNESS REQUIRED TO PREVENT PERFORATION OF THE SPACE STATION BY ORBITAL DEBRIS Final Report
William Keith Rule Dec. 1991 25 p
(Contract NAS8-38555)
(NASA-CR-193825; NAS 1.26:193825; BER-550-248) Avail: CASI HC A03/MF A01

A computer program called BALLIST that is intended to be a design tool for engineers is described. BALLIST empirically predicts the bumper thickness required to prevent perforation of the Space Station pressure wall by a projectile (such as orbital debris) as a function of the projectile's velocity. 'Ballistic' limit curves (bumper thickness vs. projectile velocity) are calculated and are displayed on the screen as well as being stored in an ASCII file. A Whipple style of spacecraft wall configuration is assumed. The predictions are based on a database of impact test results. NASA/Marshall Space Flight Center currently has the capability to generate such test results. Numerical simulation results of impact conditions that can not be tested (high velocities or large particles) can also be used for predictions. Author (revised)

The experience gained with the European Communication System (ECS) satellites during the eight years of service in orbit is summarized. The performance of individual satellite systems is evaluated. They include reports on: thermal control, communications payload, number of operating hours, telemetry, tracking, command, solar arrays, batteries, attitude control, orbit control, and reaction control. In the reporting period, the ECS system accumulated a total of 292,618 channel hours. The total outage due to spurious switchoffs was 83 channel minutes, of which 69 channel minutes were due to a front-end failure in ECS-5. ESA

SECONDARY IMPACT HAZARD ASSESSMENT Final Report, 1 Jun. 1985 - 1 Jun. 1986
1 Jun. 1986 343 p
(NASA Order T-256M)
(NASA-CR-188261; NAS 1.26:188261; Rept-86-128) Avail: CASI HC A15/MF A03

A series of light gas gun shots (4 to 7 km/sec) were performed with 5 mg nylon and aluminum projectiles to determine the size, mass, velocity, and spatial distribution of spall and ejecta from a number of graphite/epoxy targets. Similar determinations were also performed on a few aluminum targets. Target thickness and material were chosen to be representative of proposed Space Station structure. The data from these shots and other information were used to predict the hazard to Space Station elements from secondary particles resulting from impacts of micrometeoroids and orbital debris on the Space Station. This hazard was quantified as an additional flux over and above the primary micrometeoroid and orbital debris flux that must be considered in the design process. In order to simplify the calculations, eject and spall mass were assumed to scale directly with the energy of the projectile. Other scaling systems may be closer to reality. The secondary particles considered are only those particles that may impact other structure immediately after the primary impact. The addition to the orbital debris problem from these primary impacts was not addressed. Data from this study should be fed into the orbital debris model to see if Space Station secondaries make a significant contribution to orbital debris. The hazard to a Space Station element from secondary particles above and beyond the micrometeoroid and orbital debris hazard is categorized in terms of two factors: (1) the 'view factor' of the element to other Space Station structure or the geometry of placement of the element, and (2) the sensitivity to damage, stated in terms of energy. Several example cases were chosen, the Space Station module windows, windows of a Shuttle docked to the Space Station, the habitat module walls, and the photovoltaic solar cell arrays. For the examples chosen the secondary flux contributed no more than 10 percent to the total flux (primary and secondary) above a given calculated critical energy. A key assumption in these calculations is that above a certain critical energy, significant damage will be done. This is not true for all structures. Double-walled, bumpered structures are an example for which damage may be reduced as energy goes up. The critical energy assumption is probably conservative, however, in terms of secondary damage. To understand why the secondary impacts seem to, in general, contribute less than 10 percent of the flux above a given critical energy, consider the case of a meteoroid impact of a given energy on a fixed, large surface. This impact results in a variety of secondary particles, all of which have much less energy than the original impact. Conservation of energy prohibits any other situation. Thus if damage is linked to a critical energy of a particle, the primary flux will always deliver particles of much greater energy. Even if all the secondary particles impacted other Space Station structures, none would have a kinetic energy more than a fraction of the primary impact energy. Author (revised)

SURFACE CHARACTERIZATION OF LDEF MATERIALS Final Technical Report, 18 Sep. 1990 - 1 Oct. 1993
J. P. Wightman and Holly Little Grammer Oct. 1993 249 p Original contains color illustrations
(Grant NAG1-1186)
(NASA-CR-194519; NAS 1.26:194519) Avail: CASI HC A11/MF A03; 8 functional color pages

The NASA Long Duration Exposure Facility (LDEF), a passive experimental satellite, was placed into low-Earth orbit by the Shuttle Challenger in Apr. 1984. The LDEF spent an unprecedented 69 months in space. The flight and recovery of the LDEF provided a wealth of information on the longterm space environmental effects of a variety of materials exposed to the low-Earth orbit environment. Surface characterization of LDEF materials included polymers, composites, thermal control paints, and aluminum. X-ray photoelectron spectroscopy (XPS), Auger electron spectroscopy (AES), scanning electron microscopy (SEM), and contact angle analysis were used to document changes in both the surface composition and surface chemistry of these materials. Detailed XPS analysis of the polymer systems, such as Kapton, polyimide polysiloxane copolymers, and fluorinated ethylene propylene thermal blankets on the backside of the LDEF revealed significant changes in both the surface composition and surface chemistry as a result of exposure to the low-Earth orbit environment. Polymer systems such as Kapton, polyimide polysiloxane copolymers, and

polysulfone showed a common trend of decreasing carbon content and increasing oxygen content with respect to the control sample. Carbon 1s curve fit XPS analysis of the composite samples, in conjunction with SEM photomicrographs, revealed significant ablation of the polymer matrix resin to expose the carbon fibers of the composite during exposure to the space environment. Surface characterization of anodized aluminum tray clamps, which were located at regular intervals over the entire LDEF frame, provided the first results to evaluate the extent of contamination with respect to position on the LDEF. The XPS results clearly showed that the amount and state of both silicon and fluorine contamination were directly dependent upon the position of the tray clamp on the LDEF.

DEGRADATION OF THE VISIBLE AND NEAR-INFRARED CHANNELS OF THE ADVANCED VERY HIGH RESOLUTION RADIOMETER ON THE NOAA-9 SPACECRAFT: ASSESSMENT AND RECOMMENDATIONS FOR CORRECTIONS
C. R. NagarajaRao, ed. Jun. 1993 34 p
(NOAA-TR-NESDIS-70) Avail: CASI HC A03/MF A01

As part of the NOAA/NASA Advanced Very High Resolution Radiometer (AVHRR) Pathfinder Calibration Working Group activities, the in-orbit degradation of the AVHRR visible (channel 1: approximately 0.58-0.68 microns) and near-infrared (channel 2: approximately 0.72-1.05 microns) channels, which do not have any onboard calibration devices, was determined for the instrument on the NOAA-9 spacecraft, using the southeastern Libyan desert (21-23 degrees N latitude; 28-29 degrees E longitude) as a time-invariant calibration target. It was found from a statistical analysis of the relevant International Cloud Climatology Project (ISCCP) B3 data obtained over the calibration target that the gains (counts/(W/m(sup 2) microns sr)) in channels 1 and 2 of this instrument had degraded at the rate of 5.9 percent and 3.5 percent per year, respectively. To facilitate the computation of corrected radiances, the variation in time of the 'slope' - defined as the reciprocal of the 'gain' - in the two channels was determined by anchoring the relative variations of the gain to the 'absolute' calibrations based on congruent path aircraft/satellite measurements made over the White Sands area of New Mexico, U.S.A., during October/November 1986. Procedural details for obtaining the correct radiances from the measured signals in the two AVHRR channels, simple user-friendly formulae, and a look-up table are given. Author (revised)

PLANETARY SYSTEM DETECTION BY POINTS Semiannual Report Nos. 1-3 and Final Report, 15 Jun. 1988 - 31 Mar. 1990
Robert D. Reasenberg Sep. 1993 18 p
(Grant NAGw-1355)
(NASA-CR-194361; NAS 1.26:194361) Avail: CASI HC A03/MF A01

The final report and semiannual reports 1, 2, and 3 in response to the study of 'Planetary System Detection by POINTS' is presented. The grant covered the period from 15 Jun. 1988 through 31 Dec. 1989. The work during that period comprised the further development and refinement of the POINTS concept. The status of the POINTS development at the end of the Grant period was described by Reasenberg in a paper given at the JPL Workshop on Space Interferometry, 12-13 Mar. 1990, and distributed as CfA Preprint 3138. That paper, 'POINTS: a Small Astrometric Interferometer,' follows as Appendix-A. Our proposal P2276-7-09, dated July 1990, included a more detailed description of the state of the development of POINTS at the end of the tenure of Grant NAGW-1355. That proposal, which resulted in Grant NAGW-2497, is included by reference. Author (revised)

SPECTRAL ANALYSIS FOR AUTOMATED EXPLORATION AND SAMPLE ACQUISITION
Susan Eberlein and Gigi Yates 1 May 1992 19 p
(NASA-CR-194095; JPL-Publ-92-1; NAS 1.26:194095) Avail: CASI HC A03/MF A01

Future space exploration missions will rely heavily on the use of complex instrument data for determining the geologic, chemical, and elemental character of planetary surfaces. One important instrument is the imaging spectrometer, which collects complete images in multiple discrete wavelengths in the visible and infrared regions of the spectrum. Extensive computational effort is required to extract information from such high-dimensional data. A hierarchical classification scheme allows multispectral data to be analyzed for purposes of mineral classification while limiting the overall computational requirements. The hierarchical classifier exploits the tunability of a new type of imaging spectrometer which is based on an acousto-optic tunable filter. This spectrometer collects a complete image in each wavelength passband without spatial scanning. It may be programmed to scan through a range of wavelengths or to collect only specific bands for data analysis. Spectral classification activities employ artificial neural networks, trained to recognize a number of mineral classes. Analysis of the trained networks has proven useful in determining which subsets of spectral bands should be employed at each step of the hierarchical classifier. The network classifiers are capable of recognizing all mineral types which were included in the training set. In addition, the major components of many mineral mixtures can also be recognized. This capability may prove useful for a system designed to evaluate data in a strange environment where details of the mineral composition are not known in advance. Author

DEVELOPMENT OF AN ADVANCED SPACECRAFT TANDEM MASS SPECTROMETER Final Report
Russell C. Drew 31 Mar. 1992 196 p
(Contract NAS8-38422; SBIR-08.10-2214A)
(NASA-CR-194195; NAS 1.26:194195) Avail: CASI HC A09/MF A03

The purpose of this research was to apply current advanced technology in electronics and materials to the development of a miniaturized Tandem Mass Spectrometer that would have the potential for future development into a package suitable for spacecraft use. The mass spectrometer to be used as a basis for the tandem instrument would be a magnetic sector instrument, of Nier-Johnson configuration, as used on the Viking Mars Lander mission. This instrument configuration would then be matched with a suitable second stage MS to provide the benefits of tandem MS operation for rapid identification of unknown organic compounds. This tandem instrument is configured with a newly designed GC system to aid in separation of complex mixtures prior to MS analysis. A number of important results were achieved in the course of this project. Among them were the development of a miniaturized GC subsystem, with a unique desorber-injector, fully temperature feedback controlled oven with powered cooling for rapid reset to ambient conditions, a unique combination inlet system to the MS that provides for both membrane sampling and direct capillary column sample transfer, a compact and ruggedized alignment configuration for the MS, an improved ion source design for increased sensitivity, and a simple, rugged tandem MS configuration that is particularly adaptable to spacecraft use because of its low power and low vacuum pumping requirements. The potential applications of this research include use in manned spacecraft like the space station as a real-time detection and warning device for the presence of potentially harmful trace contaminants of the spacecraft atmosphere, use as an analytical device for evaluating samples collected on the Moon or a planetary surface, or even use in connection with monitoring potentially hazardous conditions that may exist in terrestrial locations such as launch pads, environmental test chambers or other sensitive areas. Commercial development of the technology could lead to a new family of environmental test instruments that would be small and portable, yet would give quick analyses of complex samples. Author

A technology development program, Astrotech 21, is being proposed by NASA to enable the launching of the next generation of space astrophysical observatories during the years 1995-2015. Astrotech 21 is being planned and will ultimately be implemented jointly by the Astrophysics Division of the Office of Space Science and Applications and the Space Directorate of the Office of Aeronautics and Space Technology. A summary of the Astrotech 21 Optical Systems Technology Workshop is presented. The goal of the workshop was to identify areas of development within advanced optical systems that require technology advances in order to meet the science goals of the Astrotech 21 mission set, and to recommend a coherent development program to achieve the required capabilities. For individual titles, see N94-14831 through N94-14838.

The Astrotech 21 Optical Systems Technology Workshop was held in Pasadena, California on March 6-8, 1991. The purpose of the workshop was to examine the state of Optical Systems Technology at the National Aeronautics Space Administration (NASA), and in industry and academia, in view of the potential Astrophysics mission set currently being considered for the late 1990's through the first quarter of the 21st century. The principal result of the workshop is this publication, which contains an assessment of the current state of the technology, and specific technology advances in six critical areas of optics, all necessary for the mission set. The workshop was divided into six panels, each of about a dozen experts in specific fields, representing NASA, industry, and academia. In addition, each panel contained expertise that spanned the spectrum from x-ray to

submillimeter wavelengths. This executive summary contains the principal recommendations of each panel. The six technology panels and their chairs were: (1) Wavefront Sensing, Control, and Pointing, Thomas Pitts, Itek Optical Systems, A Division of Litton; (2) Fabrication, Roger Angel, Steward Observatory, University of Arizona; (3) Materials and Structures, Theodore Saito, Lawrence Livermore National Laboratory; (4) Optical Testing, James Wyant, WYKO Corporation; (5) Optical Systems Integrated Modeling, Robert R. Shannon, Optical Sciences Center, University of Arizona; and (6) Advanced Optical Instruments Technology, Michael Shao, Jet Propulsion Laboratory, California Institute of Technology. This Executive Summary contains the principal recommendations of each panel. Author

The Astrophysics Division within the NASA Office of Space Science and Applications (OSSA) has defined a set of flagship and intermediate missions that are presently under study for possible launch during the next 20 years. These missions and tentative schedules, referred to as the Astrotech 21 Mission Set, are summarized. The missions are in three groups corresponding to the cognizant science branch within the Astrophysics Division. Phase C/D refers to the pre-launch construction and delivery of the spacecraft, and the Operations Phase refers to the period when the mission is active in space. Approximately 1.5 years before the start of Phase C/D, a non-advocate review (NAR) is held to ensure that the mission/system concept and the requisite technology are at an appropriate stage of readiness for full scale development to begin. Therefore, technology development is frozen (usually) as of the date of a successful NAR. An overview of the technology advances required for each of the three wavelength groups is provided in the following paragraphs, along with a brief description of the individual missions. Author (revised)

A majority of future NASA astrophysics missions from orbiting interferometers to 16-m telescopes on the Moon have, as a common requirement, the need to bring light from a large entrance aperture to the focal plane in a way that preserves the spatial coherence properties of the starlight. Only by preserving the phase of the incoming wavefront, can many scientific observations be made, observations that range from measuring the red shift of quasi-stellar objects (QSO's) to detecting the IR emission of a planet in orbit around another star. New technologies for wavefront sensing, control, and pointing hold the key to advancing our observatories of the future from those already launched or currently under development. As the size of the optical system increases, either to increase the sensitivity or angular resolution of the instrument, traditional technologies for maintaining optical wavefront accuracy become prohibitively expensive or completely impractical. For space-based instruments, the low mass requirement and the large temperature excursions further challenge existing technologies. The Hubble Space Telescope (HST) is probably the last large space telescope to rely on passive means to keep its primary optics stable and the optical system aligned. One needs only look to the significant developments in wavefront sensing, control, and pointing that have occurred over the past several years to appreciate the potential of this technology for transforming the capability of future space observatories. Future developments in space-borne telescopes will be based in part on developments in ground-based systems. Telescopes with rigid primary mirrors much larger than 5 m in diameter are impractical because of gravity loading. New technologies are now being introduced, such as active optics, that address the scale problem and that allow very large telescopes to be built. One approach is a segmented design such as that being pioneered by the W.M. Keck telescope now under construction at the Mauna Kea Observatory. It consists of 36 hexagonal mirror segments, supported on a framework structure, which are positioned by actuators located between the structure and the mirrors. The figure of the telescope is initialized by making observations of a bright star using a Shack Hartmann sensor integrated with a white light interferometer. Then, using sensed data from the mirror edges to control these actuators, the figure of the mosaic of 36 segments is maintained as if it were a rigid primary mirror. Another active optics approach is the use of a thin meniscus mirror with actuators. This technique was demonstrated on the European Southern Observatory's New Technology Telescope (NTT) and is planned for use in the Very Large Telescope (consists of four 8-m apertures), which is now entering the design phase. FABRICATION
Roger Angel (Arizona Univ., Tucson.), Richard Helms (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Jim Bilbro, Norman Brown (Lawrence Livermore National Lab., CA.), Sverre Eng (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Steve Hinman (Eastman Kodak Co., Rochester, NY.), Greg Hull-Allen (United Technologies Optical Systems, Inc., Albuquerque, NM.), Stephen Jacobs (Rochester Univ., NY.), Robert Keim (Eastman Kodak Co., Rochester, NY.), and Melville Ulmer (Northwestern Univ., Evanston, IL.) et al *In* JPL, Workshop Proceedings: Optical Systems Technology for Space Astrophysics in the 21st Century, Volume 3 15 Aug. 1992 p 59-83 (For primary document see N94-14830 02-19)
Avail: CASI HC A03/MF A02; 1 functional color page

What aspects of optical fabrication technology need to be developed so as to facilitate existing planned missions, or enable new ones? Throughout the submillimeter to UV wavelengths, the common goal is to push technology to the limits to make the largest possible apertures that are diffraction limited. At any one wavelength, the accuracy of the surface must be better than lambda/30 (rms error). The wavelength range is huge, covering four orders of magnitude from 1 mm to 100 nm. At the longer wavelengths, diffraction limited surfaces can be shaped with relatively crude techniques. The challenge in their fabrication is to make as large as possible a reflector, given the weight and volume constraints of the launch vehicle. The limited cargo diameter of the shuttle has led in the past to emphasis on deployable or erectable concepts such as the Large Deployable Reflector (LDR), which was studied by NASA for a submillimeter astrophysics mission. Replication techniques that can be used to produce light, low-cost reflecting panels are of great interest for this class of mission. At shorter wavelengths, in the optical and ultraviolet, optical fabrication will tax to the limit the most refined polishing methods. Methods of mechanical and thermal stabilization of the substrate will be severely stressed. In the thermal infrared, the need for large aperture is tempered by the even stronger need to control the telescope's thermal emission by cooled or cryogenic operation. Thus, the SIRTF mirror at 1 meter is not large and does not require unusually high accuracy, but the fabrication process must produce a mirror that is the right shape at a temperature of 4 K. Future large cooled mirrors will present more severe problems, especially if they must also be accurate enough to work at optical wavelengths. At the very shortest wavelengths accessible to reflecting optics, in the x-ray domain, the very low count fluxes of high energy photons place a premium on the collecting area. It is not necessary to reach or even approach the diffraction limit, which would demand subnanometer fabrication and figure control. Replication techniques that produce large very lightweight surfaces are of interest for x-ray optics just as they are for the submillimeter region. Optical fabrication requirements are examined in more detail for missions in each of the three spectral regions of interest in astrophysics. Author (revised)

Ghanim Al-Jamily (Barr Associates, Inc., Concord, MA.), Joe Arnold (United Technologies Optical Systems, Inc., Albuquerque, NM.), Troy Barbee (Lawrence Livermore National Lab., CA.), Dan Coulter (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Ben Dolgin (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Buck Fichter, Patricia George (Aerojet-General Corp., Azusa, CA.), and Paul Gorenstein (Harvard-Smithsonian Center for Astrophysics, Cambridge, MA.) et al *In* JPL, Workshop Proceedings: Optical Systems Technology for Space Astrophysics in the 21st Century, Volume 3 15 Aug. 1992 p 85-97 (For primary document see N94-14830 02-19)

Avail: CASI HC A03/MF A02; 1 functional color page

Materials and structures technology covers a wide range of technical areas. Some of the most pertinent issues for the Astrotech 21 missions include dimensionally stable structural materials, advanced composites, dielectric coatings, optical metallic coatings for low scattered light applications, low scattered light surfaces, deployable and inflatable structures (including optical), support structures in 0-g and 1-g environments, cryogenic optics, optical blacks, contamination hardened surfaces, radiation hardened glasses and crystals, mono-metallic telescopes and instruments, and materials characterization. Some specific examples include low coefficients of thermal expansion (CTE) structures (0.01 ppm/K), lightweight thermally stable mirror materials, thermally stable optical assemblies, high reliability/accuracy (1 micron) deployable structures, and characterization of nanometer level behavior of materials/structures for interferometry concepts. Large filled-aperture concepts will require materials with CTE's of 10(exp 9) at 80 K, anti-contamination coatings, deployable and erectable structures, composite materials with CTE's less than 0.01 ppm/K and thermal hysteresis, 0.001 ppm/K. Gravitational detection systems such as LAGOS will require rigid/deployable structures, dimensionally stable components, lightweight materials with low conductivity, and high stability optics. The Materials and Structures panel addressed these issues and the relevance of the Astrotech 21 mission requirements by dividing materials and structures technology into five categories. These categories, the necessary development, and applicable mission/program development phasing are summarized. For each of these areas, technology assessments were made and development plans were defined. Author (revised)

OPTICAL TESTING

James Wyant (WYKO Corp., Tucson, AZ.), Eric Hochberg (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Robert Breault (Breault Research Organization, Tucson, AZ.), John Greivenkamp (Arizona Univ., Tucson.), Gary Hunt, Pete Mason (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), James McGuire (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Aden Meinel (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Mike Morris (Rochester Univ., NY.), and Larry Scherr (Aerojet Electrosystems Co., Azusa, CA.) et al *In* JPL, Workshop Proceedings: Optical Systems Technology for Space Astrophysics in the 21st Century, Volume 3 15 Aug. 1992 p 99-121 (For primary document see N94-14830 02-19)

Avail: CASI HC A03/MF A02; 1 functional color page

Optical testing is one of the most vital elements in the process of preparing an optical instrument for launch. Without well understood, well controlled, and well documented test procedures, current and future mission goals will be jeopardized. We should keep in mind that the reason we test is to provide an opportunity to catch errors, oversights, and problems on the ground, where solutions are possible and difficulties can be rectified. Consequently, it is necessary to create tractable test procedures that truly provide a measure of the performance of all optical elements and systems under conditions which are close to those expected in space. Where testing is not feasible, accurate experiments are required in order to perfect models that can exactly predict the optical performance. As we stretch the boundaries of technology to perform more complex space and planetary investigations, we must expand the technology required to test the optical components and systems which we send into space. As we expand the observational wavelength ranges, so must we expand our range of optical sources and detectors. As we increase resolution and sensitivity, our understanding of optical surfaces to accommodate more stringent figure and scatter requirements must expand. Only with research and development in these areas can we hope to achieve success in the ever increasing demands made on optical testing by the highly sophisticated missions anticipated over the next two decades. Technology assessment and development plan for surface figure, surface roughness, alignment, image quality, radiometric quantities, and stray light measurement are presented. Author (revised)

An integrated modeling capability that provides the tools by which entire optical systems and instruments can be simulated and optimized is a key technology development, applicable to all mission classes, especially astrophysics. Many of the future missions require optical systems that are physically much larger than anything flown before and yet must retain the characteristic sub-micron diffraction limited wavefront accuracy of their smaller precursors. It is no longer feasible to follow the path of 'cut and test' development; the sheer scale of these systems precludes many of the older techniques that rely upon ground evaluation of full size engineering units. The ability to accurately model (by computer) and optimize the entire flight system's integrated structural, thermal, and dynamic characteristics is essential. Two distinct integrated modeling capabilities are required. These are an initial design capability and a detailed design and optimization system. The content of an initial design package is shown. It would be a modular, workstation based code which allows preliminary integrated system analysis and trade studies to be carried out quickly by a single engineer or a small design team. A simple concept for a detailed design and optimization system is shown. This is a linkage of interface architecture that allows efficient interchange of information between existing large specialized optical, control, thermal, and structural design codes. The computing environment would be a network of large mainframe machines and its users would be project level design teams. More advanced concepts for detailed design systems would support interaction between modules and automated optimization of the entire system. Technology assessment and development plans for integrated package for initial design, interface development for detailed optimization, validation, and modeling research are presented. The science objectives for proposed NASA missions for the next decades push the state of the art in sensitivity and spatial resolution over a wide range of wavelengths, including the x-ray to the submillimeter. While some of the proposed missions are larger and more sensitive versions of familiar concepts, such as the next generation space telescope, others use concepts, common on the Earth, but new to space, such as optical interferometry, in order to provide spatial resolutions impossible with other concepts. However, despite their architecture, the performance of all of the proposed missions depends critically on the back-end instruments that process the collected energy to produce scientifically interesting outputs.

The Advanced Optical Instruments Technology panel was chartered with defining technology development plans that would best improve optical instrument performance for future astrophysics missions. At this workshop the optical instrument was defined as the set of optical components that reimage the light from the telescope onto the detectors to provide information about the spatial, spectral, and polarization properties of the light. This definition was used to distinguish the optical instrument technology issues from those associated with the telescope, which were covered by a separate panel. The panel identified several areas for optical component technology development: diffraction gratings; tunable filters; interferometric beam combiners; optical materials; and fiber optics. The panel also determined that stray light suppression instruments, such as coronagraphs and nulling interferometers, were in need of general development to support future astrophysics needs. SOLAR DYNAMIC POWER SYSTEM DEVELOPMENT FOR SPACE STATION FREEDOM
Jul. 1993 156 p Sponsored by NASA. Washington
(RTOP 474-52-10)
(NASA-RP-1310; E-7059; NAS 1.61:1310) Avail: CASI HC A08/MF A02

The development of a solar dynamic electric power generation system as part of the Space Station Freedom Program is documented. The solar dynamic power system includes a solar concentrator, which collects sunlight; a receiver, which accepts and stores the concentrated solar energy and transfers this energy to a gas; a Brayton turbine, alternator, and compressor unit, which generates electric power; and a radiator, which rejects waste heat. Solar dynamic systems have greater efficiency and lower maintenance costs than photovoltaic systems and are being considered for future growth of Space Station Freedom. Solar dynamic development managed by the NASA Lewis Research Center from 1986 to Feb. 1991 is covered. It summarizes technology and hardware development, describes 'lessons learned', and, through an extensive bibliography, serves as a source list of documents that provide details of the design and analytic results achieved. It was prepared by the staff of the Solar Dynamic Power System Branch at the NASA Lewis Research Center in Cleveland, Ohio. The report includes results from the prime contractor as well as from in-house efforts, university grants, and other contracts. Also included are the writers' opinions on the best way to proceed technically and programmatically with solar dynamic efforts in the future, on the basis of their experiences in this program. NUCLEAR PROPULSION SYSTEMS ENGINEERING
W. W. Madsen, J. E. Neuman, and D. H. VanHaften 1992 11 p Presented at the Nuclear Technologies for Space Exploration Conference, Jackson, WY, 16-19 Aug. 1992
(Contract DE-AC07-76ID-01570)
(DE93-010791; EGG-M-92502; CONF-920803-17) Avail: CASI HC A03/MF A01

The Nuclear Energy for Rocket Vehicle Application (NERVA) program of the 1960's and early 1970's was dramatically successful, with no major failures during the entire testing program. This success was due in large part to the successful development of a systems engineering process. Systems engineering, properly implemented, involves all aspects of the system design and operation, and leads to optimization of the entire system: cost, schedule, performance, safety, reliability, function, requirements, etc. The process must be incorporated from the very first and continued to project completion. This paper will discuss major aspects of the NERVA systems engineering effort and consider the implications for current nuclear propulsion efforts. DOE

REAL TIME RADIOGRAPHY OF TITAN 4 BOOSTER
M. LaChapell, D. Turner, K. Dolan, D. Perkins, and B. Costerus Apr. 1993 5 p
(Contract W-7405-eng-48)
(DE93-012450; UCRL-ID-113846) Avail: CASI HC A01/MF A01

Lawrence Livermore National Laboratory successfully completed a real-time radiography of the Titan 4 booster motor in February 1993. The success of this project depended on the quick response to Air Force criteria and securing a multi-disciplinary team addressing the numerous technical challenges. The team's challenges included the following: large area imager design and fabrication problems; vibrating mitigation obstacles; sound mitigation dilemmas; high levels of fail safe confidence; and operating a fragile, transportable x-ray linear accelerator. The data was viewed in real-time and stored utilizing standard video hardware. The data from the test is presently being analyzed. The multi-disciplinary team was presented with many serious technical challenges that needed to be addressed expeditiously. The purpose of this paper is to examine some of the technical issues and how they were executed. DOE

EFFECTS OF HYDROGEN ADDITION ON COMBUSTION PERFORMANCE OF A LOX/KEROSENE ROCKET [SUISO WO KONSHOU SHITA EKITAI SANSO-KEROSHIN ROKET TO NO NENSHOU TOKUSEI]
Fumiei Ono, Hiroshi Tamura, Akinaga Kumakawa, Hiroshi Sakamoto, Kazuo Sato, Masaki Sasaki, and Nobuyuki Yatsuyanagi Sep. 1992 18 p In JAPANESE
(NAL-TR-1177; JTN-93-80496) Avail: CASI HC A03/MF A01

The effect of the addition of hydrogen on the combustion performance of a LOX/kerosene rocket combustor was experimentally studied. Combustors with a seven kN thrust force at a nominal chamber pressure of 10 MPa were employed for the firing tests. Liquid Oxygen (LOX) and kerosene (RJ-1J) were used as the main propellants and gaseous hydrogen was added as auxiliary fuel. Two types of Fuel Oxidizer Fuel (FOF) triplet injectors (type A, type B) and one type of Oxidizer Fuel Oxidizer (OFO) triplet injector (type C) were used for main propellants injection. Hydrogen was added to each combustor either from a slit located on the chamber wall near the injector face (type A) or through the injector's porous face plate (type B, type C). The mass fraction of hydrogen to the total amount of fuel was varied from zero to 13 percent. Results indicated that such hydrogen to LOX/kerosene combustion does not improve combustor efficiency, e.g., when FOF injectors (type A, type B) were used and 10 percent hydrogen was added, combustion efficiency decreased by approximately two percent. In addition, when the OFO injector (type C) was used and hydrogen was added through the injector face, the combustion efficiency remained the same under all test conditions.. Author (NASDA)

Benchmark analyses have been performed of Particle Bed Reactor (PBR) critical experiments (CX) using the MCNP radiation transport code. The experiments have been conducted at the Sandia National Laboratory reactor facility in support of the Space Nuclear Thermal Propulsion (SNTP) program. The test reactor is a nineteen element water moderated and reflected thermal system. A series of integral experiments have been carried out to test the capabilities of the radiation transport codes to predict the performance of PBR systems. MCNP was selected as the preferred radiation analysis tool for the benchmark experiments. Comparison between experimental and calculational results indicate very good agreement. This paper describes the analyses of benchmark experiments designed to quantify the accuracy of the MCNP radiation transport code for predicting the performance characteristics of PBR reactors. DOE

DESIGN, QUALIFICATION AND OPERATION OF NUCLEAR ROCKETS FOR SAFE MARS MISSIONS

D. Buden, W. W. Madsen, T. S. Olson, and L. R. Redd (Department of Energy, Idaho Falls, ID.) 1993 10 p Presented at the 10th Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 10-14 Jan. 1993

(Contract DE-AC07-76ID-01570)

(DE93-010792; EGG-M-92569; CONF-930103-31) Avail: CASI HC A02/MF A01

Nuclear thermal propulsion modules planned for use on crew missions to Mars improve mission reliability and overall safety of the mission. This is greatly enhanced if the system specifications take into account safety from initiation of the design. For instance, the use of multiple engines in the propulsion module can lead to very high system safety and reliability. Operational safety enhancements may include the following: the use of multiple perigee burns, thus allowing time to ensure that all systems are functioning properly prior to departure from Earth orbit; the ability to perform all other parts of the mission in a degraded mode with little or no degradation of the mission; and the safe disposal of the nuclear propulsion module in a heliocentric orbit out of the ecliptic plane. The standards used to qualify nuclear rockets are one of the main cost drivers of the program. Concepts and systems that minimize cost and risk will rely on use of the element and component levels to demonstrate technology readiness and validation. Subsystem or systems testing then is only needed for verification of performance. Also, these will be the safest concepts because they will be more thoroughly understood, and the safety margins will be well established and confirmed by tests. DOE

GENERATION OF NEUTRONIC THERMAL DATA IN SUPPORT OF SPACE NUCLEAR PROPULSION

S. Mughabghab, E. Schmidt, and H. Ludewig 1993 8 p Presented at the 10th Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 10-14 Jan. 1993

(Contract DE-AC02-76CH-00016)

(DE93-013148; BNL-48540; CONF-930103-37) Avail: CASI HC A02/MF A01

The scattering kernel data for (sup 7)LiH have been generated for the first time in the temperature range 50-1000 K. This is based on a phonon distribution function derived from both experimental data and theoretical calculations. A detailed study of the variation of the moderator temperature coefficient alpha(sub m)(T) with temperature, T, is carried out for a typical space nuclear reactor of the particle bed type. It is established that the moderator temperature coefficient due to chemical binding effects follows the relationship alpha(sub m)(T) = C F(sub v)(H)(sup 1.6) where F(sub v)(H) is the volume fraction of bound solid hydrogen and C is a normalization constant which depends on the moderator capture thermal cross section. The value 1.65 is to be compared with 1.54 plus/minus 0.06 derived in a previous study where water scattering kernels are applied. For control and safety reasons, a minimization of this positive component temperature coefficient can be most effective by operating the moderator at high temperatures. Advantages of this approach are outlined. In addition, suggestions are made to render the overall temperature coefficient negative. DOE

ELECTRIC PROPULSION SYSTEM TECHNOLOGY Annual Report, 1990

John R. Brophy, Charles E. Garner, and Keith D. Goodfellow Dec. 1991 185 p

(NASA-CR-194100; JPL-Publ-91-16; NAS 1.26:194100) Avail: CASI HC A09/MF A02

The work performed on the Ion Propulsion System Technology Task in FY90 is described. The objectives of this work fall under two broad categories. The first of these deals with issues associated with the application of xenon ion thrusters for primary propulsion of planetary spacecraft, and the second with the investigation of technologies which will facilitate the development of larger, higher power ion thrusters to support more advanced mission applications. Most of the effort was devoted to investigation of the critical issues associated with the use of ion thrusters for planetary spacecraft. These issues may be succinctly referred to as life time, system integration, and throttling. Chief among these is the engine life time. If the engines do not have sufficient life to perform the missions of interest, then the other issues become unimportant. Ion engine life time was investigated through two experimental programs: an investigation into the reduction of ion engine internal sputter erosion through the addition of small quantities of nitrogen, and a long duration cathode life test. In addition, a literature review and analysis of accelerator grid erosion were performed. The nitrogen addition tests indicated that the addition of between 0.5 and 1.0 percent of nitrogen by mass to the xenon propellant results in a reduction in the sputter erosion of discharge chamber components by a factor of between 20 and 50, with negligible reduction in thruster performance. The long duration test of a 6.35-mm dia. xenon hollow cathode is still in progress, and has accumulated more than 4,000 hours of operation at an emission current of 25 A at the time of this writing. One of the major system integration issues concerns possible interactions of the ion thruster produced charge exchange plasma with the spacecraft. A computer model originally developed to describe the behavior of mercury ion thruster charge exchange plasmas was resurrected and modified for xenon propellant. This model enables one to calculate the flow direction and local density of the charge exchange plasma, and indicates the degree to which this plasma can flow upstream of the thruster exhaust plane. A continuing effort to investigate the most desirable throttling technique for noble gas ion thrusters concentrated this year on experimentally determining the fixed flow rate throttling range of a 30-cm dia. thruster with a two-grid accelerator system. These experiments demonstrated a throttling capability which covers a 2.8 to 1 variation in input power. This throttling range is 55 percent greater than expected, and is due to better accelerator system performance at low net-to-total voltage ratios than indicated in the literature. To facilitate the development of large, higher power ion thrusters several brief studies were performed. These include the development of a technique which simulates ion thruster operation without beam extraction, the development of an optical technique to measure ion thruster grid distortion due to thermal expansion, tests of a capacitance measurement technique to quantify the accelerator system grid separation, and the development of a segmented thruster geometry which enables near term development of ion thrusters at power levels greater than 100 kW. Finally, a paper detailing the benefits of electric propulsion for the Space Exploration Initiative was written.

ELECTRIC PROPULSION SYSTEM TECHNOLOGY Annual Report, 1991

John R. Brophy, Charles E. Garner, Keith D. Goodfellow, Thomas J. Pivirotto, and James E. Polk Nov. 1992 153 p

(NASA-CR-194099; JPL-Publ-92-10; NAS 1.26:194099) Avail: CASI HC A08/MF A02

The work performed in fiscal year (FY) 1991 under the Propulsion Technology Program RTOP (Research and Technology Objectives and Plans) No. (55) 506-42-31 for Low-Thrust Primary and Auxiliary Propulsion technology development is described. The objectives of this work fall under two broad categories. The first of these deals with the development of ion engines for primary propulsion in support of solar system exploration. The second with the advancement of steady-state magnetoplasmadynamic (MPD)

thruster technology at 100 kW to multimegawatt input power levels. The major technology issues for ion propulsion are demonstration of adequate engine life at the 5 to 10 kW power level and scaling ion engines to power levels of tens to hundreds of kilowatts. Tests of a new technique in which the decelerator grid of a three-grid ion accelerator system is biased negative of neutralizer common potential in order to collect facility induced charge-exchange ions are described. These tests indicate that this SAND (Screen, Accelerator, Negative Decelerator) configuration may enable long duration ion engine endurance tests to be performed at vacuum chamber pressures an order of magnitude higher than previously possible. The corresponding reduction in pumping speed requirements enables endurance tests of 10 kW class ion engines to be performed within the resources of existing technology programs. The results of a successful 5,000-hr endurance of a xenon hollow cathode operating at an emission current of 25 A are described, as well as the initial tests of hollow cathodes operating on a mixture of argon and 3 percent nitrogen. Work performed on the development of carbon/carbon grids, a multi-orifice hollow cathode, and discharge chamber erosion reduction through the addition of nitrogen are also described. Critical applied-field MPD thruster technical issues remain to be resolved, including demonstration of reliable steady-state operation at input powers of hundreds to thousands of kilowatts, achievement of thruster efficiency and specific impulse levels required for missions of interest, and demonstration of adequate engine life at these input power, efficiency, and specific impulse levels. To address these issues we have designed, built, and tested a 100 kW class, radiation-cooled applied-field MPD thruster and a unique dual-beam thrust stand that enables separate measurements of the applied- and self-field thrust components. We have also initiated the development of cathode thermal and plasma sheath models that will eventually be used to guide the experimental program. In conjunction with the cathode modeling, a new cathode test facility is being constructed. This facility will support the study of cathode thermal behavior and erosion mechanisms, the diagnosis of the near-cathode plasma and the development and endurance testing of new, high-current cathode designs. To facilitate understanding of electrode surface phenomenon, we have implemented a telephoto technique to obtain photographs of the electrodes during engine operation. In order to reduce the background vacuum tank pressure during steady-state engine operation in order to obtain high fidelity anode thermal data, we have developed and are evaluating a gas-dynamic diffuser. A review of experience with alkali metal propellants for MPD thrusters led to the conclusion that alkali metals, particularly lithium, offer the potential for significant engine performance and lifetime improvements. These propellants are also condensible at room temperature, substantially reducing test facility pumping requirements. The most significant systems-level issue is the potential for spacecraft contamination. Subsequent experimental and theoretical efforts should be directed toward verifying the performance and lifetime gains and characterizing the thruster flow field to assess its impact on spacecraft surfaces. Consequently, we have begun the design and development of a new facility to study engine operation with alkali metal propellants. Author (revised)

The performance characteristics of several propulsion technologies applied to piloted Mars missions are compared. The characteristics that are compared are Initial Mass in Low Earth Orbit (IMLEO), mission flexibility, and flight times. The propulsion systems being compared are both demonstrated and envisioned: Chemical (or Cryogenic), Nuclear Thermal Rocket (NTR) solid core, NTR gas core, Nuclear Electric Propulsion (NEP), and a mirror fusion space propulsion system. The proposed magnetic mirror fusion reactor, known as the Mirror Fusion Propulsion System (MFPS), is described. The description is an overview of a design study that was conducted to convert a mirror reactor experiment at Lawrence Livermore National Lab (LLNL) into a viable space propulsion system. Design principles geared towards minimizing mass and maximizing power available for thrust are identified and applied to the LLNL reactor design, resulting in the MFPS. The MFPS' design evolution, reactor and fuel choices, and system configuration are described. Results of the performance comparison shows that the MFPS minimizes flight time to 60 to 90 days for flights to Mars while allowing continuous return-home capability while at Mars. Total MFPS IMLEO including propellant and payloads is kept to about 1,000 metric tons. Author

Nickel-hydrogen (NiH2) batteries are finding more applications in the aerospace energy storage. Since 1983, NiH2 batteries have become the primary energy storage system used for Geosynchronous-Orbit (GEO) Satellites. The first NASA application for NiH2 batteries was the Low Earth Orbit (LEO) Hubble Space Telescope Satellite launched in 1990. The handbook was prepared as a reference book to aid in the application of this technology. That is, to aid in the cell and battery design, procurement, testing, and handling of NiH2 batteries. The design of individual pressure vessel NiH2 cells is covered in Chapter I. LEO and GEO applications and their requirements are discussed in Chapter 2. The design of NiH2 batteries for both GEO and LEO applications is discussed in Chapter 3. Advanced design concepts such as the common pressure vessel and bipolar NiH2 batteries are described in Chapter 4. Performance data are presented in Chapter 5. Storage and handling of the NiH2 cells and batteries are discussed in Chapter 6. Standard test procedures are presented in Chapter 7. Cell and battery procurements are discussed in Chapter 8. Finally, safety procedures are discussed in Chapter 9. Author (revised)

Fission nuclear power is foreseen as the source for electricity in planetary colonization and exploration. This report discusses a six module, gas-cooled, cermet-fueled reactor which is proposed to meet the design objectives. The highly enriched core is compact and can operate at high temperatures for long periods of time. The helium coolant powers six modular Brayton cycles that compare favorably with the SP-100-based Brayton cycle. DOE

(Contract NAS3-25266; RTOP 506-42-31)
(NASA-CR-191187; AIAA Paper 93-2391; E-8099; NAS 1.26:191187)
Avail: CASI HC A03/MF A01

Pulsed magnetoplasmadynamic (MPD) thruster systems were analyzed for application to solar-electric orbit transfer vehicles at power levels ranging from 10 to 40 kW. Potential system level benefits of pulsed propulsion technology include ease of power scaling without thruster performance changes, improved transportability from low power flight experiments to operational systems, and reduced ground qualification costs. Required pulsed propulsion system components include a pulsed applied-field MPD thruster,

a pulse-forming network, a charge control unit, a cathode heater supply, and high speed valves. Mass estimates were obtained for each propulsion subsystem and spacecraft component using off-the-shelf technology whenever possible. Results indicate that for payloads of 1000 and 2000 kg pulsed MPD thrusters can reduce launch mass by between 1000 and 2500 kg over those achievable with hydrogen arcjets, which can be used to reduce launch vehicle class and the associated launch cost. While the achievable mass savings depends on the trip time allowed for the mission, cases are shown in which the launch vehicle required for a mission is decreased from an Atlas IIAS to an Atlas I or Delta 7920. Three electromagnetic propulsion technologies, solid propellant pulsed plasma thrusters (PPT), magnetoplasmadynamic (MPD) thrusters, and pulsed inductive thrusters (PIT), were developed for application to auxiliary and primary spacecraft propulsion. Both the PPT and MPD thrusters were flown in space, though only PPT's were used on operational satellites. The performance of operational PPT's is quite poor, providing only approximately 8 percent efficiency at approximately 1000 s specific impulse. However, laboratory PPT's yielding 34 percent efficiency at 2000 s specific impulse were extensively tested, and peak performance levels of 53 percent efficiency at 5170 s specific impulse were demonstrated. MPD thrusters were flown as experiments on the Japanese MS-T4 spacecraft and the Space Shuttle and were qualified for a flight in 1994. The flight MPD thrusters were pulsed, with a peak performance of 22 percent efficiency at 2500 s specific impulse using ammonia propellant. Laboratory MPD thrusters were demonstrated with up to 70 percent efficiency and 700 s specific impulse using lithium propellant. While the PIT thruster has never been flown, recent performance measurements using ammonia and hydrazine propellants are extremely encouraging, reaching 50 percent efficiency for specific impulses between 4000 to 8000 s. The fundamental operating principles, performance measurements, and system level design for the three types of electromagnetic thrusters are reviewed, and available data on flight tests are discussed for the PPT and MPD thrusters. ELECTRICAL ACTUATION TECHNOLOGY BRIDGING
Monica Hammond, comp. and John Sharkey, comp. Washington May 1993 753 p Workshop held in Huntsville, AL, 29 Sep. - 1 Oct. 1992 Original contains color illustrations
(NASA-CP-3213; M-720; NAS 1.55:3213) Avail: CASI HC A99/MF A06; 15 functional color pages

This document contains the proceedings of the NASA Electrical Actuation Technology Bridging (ELA-TB) Workshop held in Huntsville, Alabama, September 29-October 1, 1992. The workshop was sponsored by the NASA Office of Space Systems Development and Marshall Space Flight Center (MSFC). The workshop addressed key technologies bridging the entire field of electrical actuation including systems methodology, control electronics, power source systems, reliability, maintainability, and vehicle health management with special emphasis on thrust vector control (TVC) applications on NASA launch vehicles. Speakers were drawn primarily from industry with participation from universities and government. In addition, prototype hardware demonstrations were held at the MSFC Propulsion Laboratory each afternoon. Splinter sessions held on the final day afforded the opportunity to discuss key issues and to provide overall recommendations. Presentations are included in this document. Author

RECENT TESTING OF 30 kW HYDROGEN ARCJET THRUSTERS
Thomas W. Haag Jun. 1993 18 p Presented at the 29th Joint Propulsion Conference and Exhibit, Monterey, CA, 28 Jun. - 1 Jul. 1993; cosponsored by AIAA, SAE, ASME, and ASEE
(RTOP 506-42-31)
(NASA-TM-106214; E-7923; NAS 1.15:106214; AIAA Paper 93-1902)
Avail: CASI HC A03/MF A01

NASA is conducting efforts to evaluate high-power hydrogen arcjets for orbit transfer propulsion applications. As part of this program, an attempt was made to reexamine both radiatively- and regeneratively-cooled, 30 kW thrusters first demonstrated by the Giannini Scientific Corp. in 1963. The arcjets were configured to force arc attachment upstream of the throat in a subsonic chamber region. While thruster currents were steady, the voltage traces exhibited sawtooth waveforms at frequencies on the order of 20 kHz. Voltage variations per cycle were typically between 100 and 310 volts, indicating major changes in the position of the arc attachment with time. When operated at their respective design points, the performance of both thrusters fell below the values listed in the 1960's development reports. The reason for the discrepancies is not currently understood and further investigations are in progress. However, the recently measured efficiencies were high compared to those obtained with constricted-arc designs at similar conditions, and further arcjet performance optimizations may be possible. ARC-HEATING TESTS OF THERMAL PROTECTION SYSTEM MATERIALS FOR THE H-2 ROCKET FAIRING [H-2 ROKETTO FEARINGU DANNETSUZAI NO AKU KANETSU SHIKEN]
Noriaki Hirabayashi, Takashi Matsuzaki, Yukio Fukushima (National Space Development Agency, Tokyo, Japan.), Tomihisa Nakamura (National Space Development Agency, Tokyo, Japan.), and Takeshi Fujita (National Space Development Agency, Tokyo, Japan.) Oct. 1992 24 p In JAPANESE
(NAL-TR-1181; JTN-93-80503) Avail: CASI HC A03/MF A01

Materials suitable for the Thermal Protection System (TPS) of the rocket fairing for the Japanese next generation launch vehicle named H-2 were tested using an arc-heated wind tunnel. The main constituents of the candidate materials were epoxy resin and silicon rubber. The heating rate was from 60 to 100 kW/(sq m) in accordance with the maximum heating rate of the nose region of an ascending H-2 rocket. Test results showed that polycondensed silicon rubber was the best candidate as the main component of the TPS, and also that a SiC coating was indispensable. In addition, based on results and a preliminary estimation of the skin temperatures of the fairing nose region, a SiC coating of about 2 mm in thickness is considered sufficient to achieve thermal protection capability. PRELIMINARY NUCLEAR SAFETY ASSESSMENT OF THE NEPST (TOPAZ 2) SPACE REACTOR PROGRAM
A. C. Marshall 1993 8 p Presented at the 2nd Specialists Conference and Short Course on Thermionic Energy Conversion, Goteborg, Sweden, 3-7 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-012853; SAND-93-1067C; CONF-9305179-1) Avail: CASI HC A02/MF A01

The United States (US) Strategic Defense Initiative Organization (SDIO) decided to investigate the possibility of launching a Russian Topaz 2 space nuclear power system. A preliminary nuclear safety assessment was conducted to determine whether or not a space mission could be conducted safely and within budget constraints. As part of this assessment, a safety policy and safety functional requirements were developed to guide both the safety assessment and future Topaz 2 activities. A review of the Russian flight safety program was conducted and documented. Our preliminary nuclear safety assessment included a number of deterministic analyses, such as the following: neutronic analysis of normal and accident configurations, an evaluation of temperature coefficients of reactivity, a reentry and disposal analysis, an analysis of postulated launch abort impact accidents, and an analysis of postulated propellant fire and explosion accidents. Based on the assessment to date, it appears that it will be possible to safely launch the Topaz 2 system in the US with a modification to preclude water flooded criticality. A full scale safety program is now underway. DOE

GAS CORE NUCLEAR THERMAL ROCKET ENGINE RESEARCH AND DEVELOPMENT IN THE FORMER USSR
M. W. Koehlinger, ed., R. G. Bennett, ed., and C. G. Motloch, ed. Sep. 1992 63 p
(Contract DE-AC07-76ID-01570)
(DE93-012165; EGG-NE-10391) Avail: CASI HC A04/MF A01

Beginning in 1957 and continuing into the mid 1970's, the USSR conducted an extensive investigation into the use of both solid and gas core nuclear thermal rocket engines for space missions. During this time the scientific and engineering problems associated with the development of a solid core engine were resolved. At the same time, research was undertaken on a gas core engine, and some of the basic engineering problems associated with the concept were investigated. At the conclusion of the program, the basic principles of the solid core concept were established. However, a prototype solid core engine was not built because no established mission required such an engine. For the gas core concept, some of the basic physical processes involved were studied both theoretically and experimentally. However, no simple method of conducting proof-of-principle tests in a neutron flux was devised. This report focuses primarily on the development of the gas core concept in the former USSR. A variety of gas core engine system parameters and designs are presented, along with a summary discussion of the basic physical principles and limitations involved in their design. The parallel development of the solid core concept is briefly described to provide an overall perspective of the magnitude of the nuclear thermal propulsion program and a technical comparison with the gas core concept. COMPUTER PROGRAM FOR THERMAL AND TRANSPORT PROPERTIES OF PARAHYDROGEN FROM 20 TO 10,000 K
James T. Walton Washington Aug. 1993 16 p
(RTOP 593-71-11)
(NASA-TP-3378; E-7594; NAS 1.60:3378) Avail: CASI HC A03/MF A01

A computer program was recently developed to provide thermal and transport properties for parahydrogen across a wide temperature and pressure range. The program, NBS+/-pH2, matches the most recent parahydrogen property data from the National Bureau of Standards up to 3000 K and property data from the NASA Lewis Research Center's Chemical Equilibrium Computer Program up to 10,000 K. The pressure range of NBS+/-pH2 is from 1 x 10(exp 4) to 1.6 x 10(exp 7) Pa. The program was developed to meet the need for accurate parahydrogen properties from liquid to dissociated conditions as required by propulsion simulation programs being developed under the Space Exploration Initiative. NBS+/-pH2 is a machine-independent, standard Fortran 77 program which provides density, thermal conductivity, viscosity, Prandtl number, entropy, specific heats, and speed of sound given pressure and either temperature or enthalpy. This program is described and a comparison to programs previously available is provided. Author (revised)

NUCLEAR THERMAL PROPULSION ENGINE BASED ON PARTICLE BED REACTOR USING LIGHT WATER STEAM AS A PROPELLANT
J. R. Powell, H. Ludewig, and G. Maise 1993 6 p Presented at the 10th Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 10-14 Jan. 1993
(Contract DE-AC02-76CH-00016)
(DE93-014336; BNL-48667; CONF-930103-40) Avail: CASI HC A02/MF A01 (US Sales Only)

In this paper the possibility of configuring a water cooled Nuclear Thermal Propulsion (NTP) rocket, based on a Particle Bed Reactor (PBR), is investigated. This rocket will be used to operate on water obtained from near earth objects. The conclusions reached in this paper indicate that it is possible to configure a PBR based NTP rocket to operate on water and meet the mission requirements envisioned for it. No insurmountable technology issues have been identified. DOE

IDENTIFICATION AND INTERPRETATION OF PATTERNS IN ROCKET ENGINE DATA Final Report, Jul. 1990 - Jul. 1993
C. F. Lo, K. Wu, and B. A. Whitehead 4 Oct. 1993 35 p
(Grant NAG8-166)
(NASA-CR-194534; NAS 1.26:194534) Avail: CASI HC A03/MF A01

A prototype software system was constructed to detect anomalous Space Shuttle Main Engine (SSME) behavior in the early stages of fault development significantly earlier than the indication provided by either redline detection mechanism or human expert analysis. The major task of the research project is to analyze ground test data, to identify patterns associated with the anomalous engine behavior, and to develop a pattern identification and detection system on the basis of this analysis. A prototype expert system which was developed on both PC and Symbolics 3670 lisp machine for detecting anomalies in turbopump vibration data was checked with data from ground tests 902-473, 902-501, 902-519, and 904-097 of the Space Shuttle Main Engine. The neural networks method was also applied to supplement the statistical method utilized in the prototype system to investigate the feasibility in detecting anomalies in turbopump vibration of SSME. In most cases the anomalies detected by the expert system agree with those reported by NASA. On the neural networks approach, the results are given the successful detection rate higher than 95 percent to identify either normal or abnormal running condition based on the experimental data as well as numerical simulation. ANALYSIS OF REACTING FLOWFIELDS IN LOW-THRUST ROCKET ENGINES AND PLUMES Ph.D. Thesis
Jonathan Mitchell Weiss 1992 196 p
Avail: Univ. Microfilms Order No. DA9311743

The mixing and combustion processes in small gaseous hydrogen-oxygen thrusters and plumes are studied by means of a computational model developed as a general purpose analytic procedure for solving low speed, reacting, internal flowfields. The model includes the full Navier-Stokes equations coupled with species diffusion equations for a hydrogen-oxygen reaction kinetics system as well as the option to use either the k-Epsilon or q-Omega low Reynolds number, two-equation turbulence models. Solution of the governing equations is accomplished by a finite-volume formulation

with central-difference spatial discretizations and an explicit, four-stage, Runge Kutta time-integration procedure. The Runge-Kutta scheme appears to provide efficient convergence when applied to the calculation of turbulent, reacting flowfields in these small thrusters. Appropriate boundary conditions are developed to properly model propellant mass flowrates and regenerative wall cooling. The computational method is validated against measured engine performance parameters on a global level, as well as experimentally obtained exit plane and plume flowfield properties on a local level. The model does an excellent job of predicting the measured performance trends of an auxiliary thruster as a function of O/F ratio, although the performance levels are consistently underpredicted by approximately 4 percent. These differences arise because the extent to which the wall coolant layer and combustion gases mix and react is underpredicted. Predictions of velocity components, temperature and species number densities in the near-field plume regions of several low-thrust engines show reasonable agreement with experimental data obtained by two separate laser diagnostic techniques. Discrepancies between the predictions and measurements are primarily due to three-dimensional mixing processes which are not accounted for in the analysis. Both comparisons with experiment and the evident reason for errors in absolute levels of predicted quantities suggest the method should prove valuable for predicting parametric trends for design studies. In addition, issues such as numerical stability, robustness and computational efficiency are addressed. These include the evaluation of a numerically compatible two-equation turbulence model and the implementation of a time-derivative preconditioning method for convergence enhancement of low Mach number, chemically reacting flows. INVESTIGATION OF THE FEASIBILITY OF OPTICAL DIAGNOSTIC MEASUREMENTS AT THE EXIT OF THE SSME Final Report
John A. Shirley and Laurence R. Boedeker 1 Jul. 1993 47 p
(Contract NAS8-36861)
(NASA-CR-193832; NAS 1.26:193832; R93-957424-F) Avail: CASI HC A03/MF A01

Under Contract NAS8-36861 sponsored by NASA Marshall Space Flight Center, the United Technologies Research Center is conducting an investigation of the feasibility of remote optical diagnostics to measure temperature, species concentration and velocity at the exit of the Space Shuttle Main Engine (SSME). This is a two phase study consisting of a conceptual design phase followed by a laboratory experimental investigation. The first task of the conceptual design studies is to screen and evaluate the techniques which can be used for the measurements. The second task is to select the most promising technique or techniques, if as expected, more than one type of measurement must be used to measure all the flow variables of interest. The third task is to examine in detail analytically the capabilities and limitations of the selected technique(s). The results of this study are described in the section of this report entitled Conceptual Design Investigations. The conceptual design studies identified spontaneous Raman scattering and photodissociative flow-tagging for measurements respectively of gas temperature and major species concentration and for velocity. These techniques and others that were considered are described in the section describing the conceptual design. The objective of the second phase of investigations was to investigate experimentally the techniques identified in the first phase. The first task of the experimental feasibility study is to design and assemble laboratory scale experimental apparatus to evaluate the best approaches for SSME exit optical diagnostics for temperature, species concentrations and velocity, as selected in the Phase I conceptual design study. The second task is to evaluate performance, investigate limitations, and establish actual diagnostic capabilities, accuracies and precision for the selected optical systems. The third task is to evaluate design requirements and system trade-offs of conceptual instruments. Spontaneous Raman scattering excited by a KrF excimer laser pulse was investigated for SSME exit plane temperature and major species concentration measurements. The relative concentrations of molecular hydrogen and water vapor would be determined by measuring the integrated Q-branch scattering signals through narrow bandpass filters in front of photomultipliers. The temperature would be determined by comparing the signal from a single hydrogen rotational Raman line to the total hydrogen Q-branch signal. The rotational Raman line would be isolated by a monochromator and detected with a PMT. Derived from text

PRIMARY AND SECONDARY ELECTRICAL SPACE POWER BASED ON ADVANCED PEM SYSTEMS
N. E. Vanderborgh, J. C. Hedstrom, K. R. Stroh, and J. R. Huff (Ballard Power Corp., Albuquerque, NM.) 1993 9 p Presented at the 4th Space Electrochemical Research and Technology Conference, Cleveland, OH, 14-15 Apr. 1993
(Contract W-7405-eng-36)
(DE93-012643; LA-UR-93-1305; CONF-9304142-1) Avail: CASI HC A02/MF A01

For new space ventures, power continues to be a pacing function for mission planning and experiment endurance. Although electrochemical power is a well demonstrated space power technology, current hardware limitations impact future mission viability. In order to document and augment electrochemical technology, a series of experiments for NASA LeRC are underway at the Los Alamos National Laboratory that define operational parameters on contemporary proton exchange membrane (PEM) hardware operating with hydrogen and oxygen reactants. Because of the high efficiency possible for water electrolysis, this hardware is also thought part of a secondary battery design built around stored reactants--the so-called regenerative fuel cell. An overview of stack testing at Los Alamos, and of analyses related to regenerative fuel cell systems are provided in this paper. Finally, this paper describes work looking at innovative concepts that remove complexity from stack hardware with the specific intent of higher system reliability. This new concept offers the potential for unprecedented electrochemical power system energy densities. DOE

Hollow cathode plasma contactors were baselined for Space Station Freedom (SSF) to control the electrical potentials of surfaces to eliminate/mitigate damaging interactions with the space environment. The system represents a dual-use technology which is a direct outgrowth of the NASA electric propulsion program and in particular the technology development effort on ion thruster systems. Specific efforts include optimizing the design and configuration of the contactor, validating its required lifetime, and characterizing the contactor plume and electromagnetic interference. The plasma contact or subsystems include the plasma contact or unit, a power electronics unit, and an expellant management unit. Under this program these will all be brought to breadboard and engineering model development status. New test facilities were developed, and existing facilities were augmented, to support characterizations and life testing of contactor components and systems. The magnitude, scope, and status of the plasma contactor hardware development program now underway and preliminary test results on system components are discussed. Author (revised)

INSOLUBLE COATINGS FOR STIRLING ENGINE HEAT PIPE CONDENSER SURFACES Final Report
Peter M. Dussinger Sep. 1993 63 p
(Contract NAS3-26325; RTOP 324-01-00)
(NASA-CR-191188; E-8101; NAS 1.26:191188) Avail: CASI HC A04/MF A01

The work done by Thermacore, Inc., Lancaster, Pennsylvania, for the Phase 1, 1992 SBIR National Aeronautics and Space Administration Contract, 'Insoluble Coatings for Stirling Engine Heat Pipe Condenser Surfaces' is described. The work was performed between January 1992 and July 1992. Stirling heat engines are being developed for electrical power generation use on manned and unmanned earth orbital and planetary missions. Dish Stirling solar systems and nuclear reactor Stirling systems are two of the most promising applications of the Stirling engine electrical power generation technology. The sources of thermal energy used to drive the Stirling engine typically are non-uniform in temperature and heat flux. Liquid metal heat pipe receivers are used as thermal transformers and isothermalizers to deliver the thermal energy at a uniform high temperature to the heat input section of the Stirling engine. The use of a heat pipe receiver greatly enhances system efficiency and potential life span. One issue that is raised during the design phase of heat pipe receivers is the potential solubility corrosion of the Stirling engine heat input section by the liquid metal working fluid. This Phase 1 effort initiated a program to evaluate and demonstrate coatings, applied to nickel based Stirling engine heater head materials, that are practically 'insoluble' in sodium, potassium, and NaK. This program initiated a study of nickel aluminide as a coating and developed and demonstrated a heat pipe test vehicle that can be used to test candidate materials and coatings. Nickel 200 and nickel aluminide coated Nickel 200 were tested for 1000 hours at 800 C at a condensation heat flux of 25 W/sq cm. Subsequent analyses of the samples showed no visible sign of solubility corrosion of either coated or uncoated samples. The analysis technique, photomicrographs at 200X, has a resolution of better than 2.5 microns (.0001 in). The results indicate that the heat pipe environment is not directly comparable to liquid metal pumped loop data, that nickel aluminide is still a leading candidate for solubility corrosion protection, and that longer duration tests are required to reach a definitive conclusion whether coatings are required at all. Should further testing be required, the test vehicle and analytical tools were developed.

SPACE REACTOR FUEL ELEMENT TESTING IN UPGRADED TREAT
M. Todosow, P. Bezler, H. Ludewig, and W. Y. Kato 1993 6 p
Presented at the 10th Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 10-14 Jan. 1993
(Contract DE-AC02-76CH-00016)
(DE93-012524; BNL-48700; CONF-930103-36) Avail: CASI HC A02/MF A01 (US Sales Only)

The testing of candidate fuel elements at prototypic operating conditions with respect to temperature, power density, hydrogen coolant flow rate, etc.; a crucial component in the development and qualification of nuclear rocket engines based on the Particle Bed Reactor (PBR); NERVA-derivative; and other concepts are discussed. Such testing may be performed at existing reactors, or at new facilities. A scoping study has been performed to assess the feasibility of testing PBR based fuel elements at the TREAT reactor. Initial results suggest that full-scale PBR elements could be tested at an average energy deposition of approximately 60-80 MW-s/L in the current TREAT reactor. If the TREAT reactor was upgraded to include fuel elements with a higher temperature limit, average energy deposition of approximately 100 MW/L may be achievable. DOE

The efficacy of CMP and CMPO (carbamoylmethylphosphonates, carbamoylmethylphosphine oxides) as extractants has stimulated interest in the design of new extractants, in particular, bifunctional and trifunctional ligands containing both P(double bond)O and N-O donors. 2,6-bis(diphenylphosphino) pyridine N,P,P-trioxide was selected as a target, with the bifunctional and trifunctional diphenylmethylphosphino analogs as alternate target ligands. The ligands were synthesized and characterized. Their coordination chemistry was studied using Pr, Tb, Yb, Th; a wider range of metal/ligand stoichiometries was found than is typically found for other ligands, and the ligands are sufficiently basic that, under some conditions, they displace nitrate ions from the inner coordination sphere, which is unusual for neutral donor ligands. For both 2:1 and 4:1 complexes, the ligand is bonded to the Ln(3) ions in a bidentate manner and in a tridentate manner for 1:1 and 2:1 complexes. These ligands may be unusually effective solvent extraction agents, and liquid-liquid extraction studies are in progress. DOE

The design and manufacture of textile composite panels, tubes, and angle sections that were provided to NASA for testing and evaluation are documented. The textile preform designs and requirements were established by NASA in collaboration with Boeing and several vendors of textile reinforcements. The following four types of preform architectures were used: stitched uniweave, 2D-braids, 3D-braids, and interlock weaves. The preforms consisted primarily of Hercules AS4 carbon fiber; Shell RSL-1895 resin was introduced using a resin transfer molding process. All the finished parts were inspected using ultrasonics. (RTOP 506-43-11)
(NASA-TM-4491; E-7689; NAS 1.15:4491) Avail: CASI HC A02/MF A01

Graphite fibers were heated in a vacuum to test the adhesion of deposited films at elevated temperatures. Copper-clad fibers and fibers with bilayer coatings were resistance heated by a direct-current power supply. Where possible, peak temperatures were measured with a long-focal-length optical pyrometer. Fiber surface wetting or nonwetting behavior could be clearly observed after this relatively quick and simple procedure. These results are discussed in the context of creating composites of graphite fibers in a copper matrix. Author (revised)

NDE OF TITANIUM ALLOY MMC RINGS FOR GAS TURBINE ENGINES

George Y. Baaklini, Larry D. Percival (Pratt and Whitney Aircraft, West Palm Beach, FL.), Robert N. Yancey (Advanced Research and Applications Corp., Dayton, OH.), and Harold E. Kautz Sep. 1993 14 p Proposed for presentation at the Tenth Biennial Conference on Reliability Stress Analysis and Failure Prevention, Albuquerque, NM, 19-22 Sep. 1993; sponsored by ASME

(RTOP 510-01-50)

(NASA-TM-106188; E-7892; NAS 1.15:106188) Avail: CASI HC A03/MF A01

Progress in the processing and fabrication of metal matrix composites (MMC's) requires appropriate mechanical and nondestructive testing methods. These methods are needed to characterize properties, assess integrity, and predict the life of engine components such as compressor rotors, blades, and vanes. Capabilities and limitations of several state-of-the-art nondestructive evaluation (NDE) technologies are investigated for characterizing titanium MMC rings for gas turbine engines. The use of NDE technologies such as x-ray computed tomography, radiography, and ultrasonics in identifying fabrication-related problems that caused defects in components is examined. Acousto-ultrasonics was explored to assess degradation of material mechanical properties by using stress wave factor and ultrasonic velocity measurements before and after the burst testing of the rings. AN ADVANCED TEST TECHNIQUE TO QUANTIFY THERMOMECHANICAL FATIGUE DAMAGE ACCUMULATION IN COMPOSITE MATERIALS Final Report

Michael G. Castelli Aug. 1993 9 p

(Contract NAS3-25266; RTOP 510-01-50)

(NASA-CR-191147; E-8068; NAS 1.26:191147) Avail: CASI HC A02/MF A01

A mechanical test technique was developed to assist in quantifying the accumulation of damage in composite materials during thermomechanical fatigue (TMF) cycling. This was accomplished by incorporating definitive elastic mechanical property measurements into an ongoing load-controlled TMF test without disturbing the test specimen or significantly altering the test conditions. The technique allows two fundamental composite properties consisting of the isothermal elastic static moduli and the macroscopic coefficient of thermal expansion (CTE) to be measured and collected as functions of the TMF cycles. The specific implementation was incorporated into the commonly employed idealized in-phase and out-of-phase TMF cycles. However, the techniques discussed could be easily implemented into any form of load-controlled TMF mission cycle. By quantifying the degradations of these properties, tremendous insights are gained concerning the progression of macroscopic composite damage and often times the progression of damage within a given constituent. This information should also be useful for the characterization and essential for the verification of analytical damage modeling methodologies. Several examples utilizing this test technique are given for three different fiber lay-ups of titanium metal matrix composites. Author

MEASUREMENT OF RESIDUAL STRAIN IN COMPOSITES BY MEANS OF TIME-OF-FLIGHT NEUTRON DIFFRACTION

D. S. Kupperman, S. Majumdar, J. Richardson, and A. Saigal 1993 16 p Presented at the 1993 Annual Meeting of the American Crystallographic Association, Albuquerque, NM, 24-28 May 1993

(Contract W-31-109-eng-38)

(DE93-012939; ANL/MCT/CP-78715; CONF-9305188-1) Avail: CASI HC A03/MF A01

Neutron diffraction time-of-flight measurements using the Intense Pulsed Neutron Source at Argonne National Laboratory have been employed to study strain in various metal- and ceramic-matrix composites. For example, measurements carried out to 900 C on a composite composed of a titanium alloy matrix and silicon carbide fibers have been used to validate theoretical assumptions in the prediction of fabrication-induced residual stress. Sapphire reinforced nickel aluminide composites have also been studied. Studies of a high-temperature ceramic superconducting composite consisting of yttrium-barium-copper-oxide and silver with various volume fractions of silver have also been carried out. The results of these studies have provided information on the effect of Ag content on interface bonding. In addition, ceramic-matrix composites with randomly dispersed ceramic whiskers with varying fiber content have been investigated. DOE

FLIGHT SERVICE EVALUATION OF COMPOSITE COMPONENTS ON THE BELL HELICOPTER MODEL 206L Final Report

Henry Wilson 1 Sep. 1993 129 p

(Contract NAS1-15279; RTOP 536-06-37-03)

(NASA-CR-191499; NAS 1.26:191499; Rept-699-099-359) Avail: CASI HC A07/MF A02

This is the final report on the advanced composite components which were placed in service on the 206L LongRanger helicopters in the continental United States, Canada, and Alaska. This report covers all test data which was gathered, as well as maintenance histories of the parts. The previous reports describe the fabrication, service experiences, and test data through 1986. This report contains information from these references, as well as data gathered after 1986. The status of the 40 sets of components is discussed. Each set consisted of a vertical fin, forward fairing, litter door, and baggage door. Almost 500,000 flight hours were accumulated on the 160 parts, with the high-time part accumulating 14,687 flight hours. Over 60 percent of the parts were destructively tested to measure strength and stiffness retention over the course of the program. The vertical fins had the greatest strength retention followed by the litter doors. The baggage doors had the poorest retention of strength. There was very little difference in property retention between the four primary operating regions: Northwest U.S., Southwest U.S., Gulf of Mexico Coastal Region, and the Northeast U.S. and Eastern Canada Region. The field problems have ranged from two lightning-struck fins to significant delaminations in the baggage doors. There was only one environmentally related field incident, in which the glass windows on the litter doors were found to loosen due to high temperatures experienced in the southwest region. INELASTIC DEFORMATION MECHANISMS IN SCS-6/Ti 15-3 MMC LAMINA UNDER COMPRESSION

Golam M. Newaz and Bhaskar S. Majumdar Cleveland, OH NASA Sep. 1993 35 p

(Contract NAS3-26494; RTOP 510-01-50)

(NASA-CR-191170; E-8085; NAS 1.26:191170) Avail: CASI HC A03/MF A01

An investigation was undertaken to study the inelastic deformation mechanisms in (0)(sub 8) and (90)(sub 8) Ti 15-3/SCS-6 lamina subjected to pure compression. Monotonic tests were conducted at room temperature (RT), 538 C and 650 C. Results indicate that mechanical response and deformation characteristics were different in monotonic tension and compression loading whereas some of those differences could be attributed to residual stress effects. There were other differences because of changes in damage and failure modes. The inelastic deformation in the (0)(sub 8) lamina under compression was controlled primarily by matrix plasticity, although some evidence of fiber-matrix debonding was observed. Failure of the specimen in compression was due to fiber buckling in a macroscopic shear zone (the failure plane). The inelastic deformation mechanisms under compression in (90)(sub 8) lamina were controlled by radial fiber fracture, matrix plasticity, and fiber-matrix debonding. The radial fiber fracture was a new damage mode observed for MMC's. Constitutive response was predicted for both the (0)(sub 8) and (90)(sub 8) laminae, using AGLPLY, METCAN, and Battelle's Unit Cell FEA model. Results from the analyses were encouraging. FRACTURE BEHAVIOR OF VANADIUM/VANADIUM SILICIDE IN-SITU COMPOSITES
M. J. Strum and G. A. Henshall 30 Nov. 1992 8 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract W-7405-eng-48)
(DE93-013422; UCRL-JC-112408; CONF-921101-119) Avail: CASI HC A02/MF A01

The fracture behavior of V-V(sub 3)Si in-situ composite alloys has been evaluated for intermetallic phase fractions of 30, 50, and 70 volume percent. In addition, the mechanical properties of the ductile constituent in these composites have been evaluated from two alloys containing silicon at its solubility-limit in vanadium at the eutectic temperature and at 1400 degrees C. The fracture toughness was found to increase monotonically with increasing volume fraction of ductile phase. Fractography has shown evidence of crack bridging by the vanadium solid solution phase and increased ductility within the composite relative to bulk measurements. The toughness results are compared with predictions based on an existing model of ductile-phase toughening using our measurements of component properties. DOE

PROCESSING AND MECHANICAL PROPERTIES OF SILICON CARBIDE PLATELET REINFORCED ALUMINA COMPOSITES Ph.D. Thesis
Yeong-Shyung Chou 1992 223 p
Avail: Univ. Microfilms Order No. DA9311611

The processing and the mechanical properties of SiC-platelet/Al2O3 composites are examined. In the processing part, the goal is to identify the effect of forming methods on the microstructural evolution, in particular, the factors that influence preferred platelet orientation. Three forming techniques - slip casting, tape casting, and dry compaction - were employed to make the composites. Optical microscopy and an x-ray device, pole-figure goniometer, were used to analyze the degree of preferred orientation. Preferred orientation was studied on samples before and after hot-pressing. The effects of aspect ratio of platelets and of die pressure were also examined. The mechanical properties studied were Young's modulus, fracture toughness, and flexural strength. The effects of the platelet size and the microstructural anisotropy were examined. The optimum mechanical properties of the composites were a Young's modulus of 421 GPa, fracture toughness of 7.77 MPa(square root of m), and a flexural strength of 480 MPa. Based on the microstructural observations, a theoretical analysis on the toughening due to crack deflection in perfectly aligned disc composites was conducted. Toughening predictions of the initial tilt and the subsequent twist were calculated. The effect of the aspect ratio and the volume fraction of platelets were also considered. To test the model and to identify the predominant toughening mechanism, electron microscopy was first used to directly find the possible toughening mechanisms. Fracture toughness was measured with the bridge indentation method and compared with the theoretical predictions. R-curve behavior was measured to clarify the toughening contribution from bridging SiC platelets. In addition, fracture surface roughness was measured to provide a semi-quantitative assessment of the crack deflection process. From the combination of fracture surface roughness measurements, microstructural observation, comparison of experimental toughness with theoretical predictions, and measurements of R-curve behavior, it was concluded that crack deflection was the major toughening mechanism in the SiC-platelet/Al2O3 composites.

NONLINEAR VIBRATIONS OF THICK COMPOSITE PLATES: HIGHER-ORDER SHEAR DEFORMATION PLATE THEORY Ph.D. Thesis
Hung-Yu Lu 1992 164 p
Avail: Univ. Microfilms Order No. DA9310835

The equations of motion and the associate boundary conditions for the nonlinear vibrations of a heterogeneous anisotropic thick annular plate are derived by using Hamilton's principle. The effects of shear deformation, rotatory inertia, inplane deformation and inplane inertia are all included to provide more accurate results for the design and analysis of annular plates. The shear deformation of the plate is assumed based on the higher-order shear deformation plate theory. Due to the complexity of the derived nonlinear coupled partial differential equations, a finite element method is used in the numerical analysis. The basic equation of motion in finite element formulation is obtained by using a variational approach. A numerical technique of using an incremental and iterative scheme is utilized for calculating frequency responses. The developed mathematical model is then applied to study axisymmetric nonlinear vibrations of various thick annular plates: homogeneous isotropic annular plates, homogeneous orthotropic annular plates, heterogeneous isotropic annular sandwich plates, and heterogeneous orthotropic annular sandwich plates. The numerical results for frequencies of each annular plate system are obtained. The effects of shear deformation and rotatory inertia are presented and discussed. The influence of lamination interchange of a heterogeneous annular sandwich plate is also demonstrated. Author

Metal matrix composites (MMC's) have been heavily studied over the past thirty years. During that period, many proposals have been made to develop a matrix alloy that was compatible with the reinforcing phase. However, for one reason or another, the technology has continued to focus on conventional alloys and fabrication practices. Although tremendous advances have been made on composite materials, the basic technology remains similar to systems studied twenty years ago. This work represents the first new program where new alloys are being developed for graphite reinforced composites which are tailored to a novel processing technology for manufacturing corrosion resistant graphite reinforced composites.

DEVELOPMENT OF TIME-DEPENDENT ORTHOTROPIC CONSTITUTIVE LAW OF A THERMOPLASTIC COMPOSITE MATERIAL Ph.D. Thesis
Chien-Chain Lia 1992 133 p
Avail: Univ. Microfilms Order No. DA9312070

Thermoplastic composite materials have been receiving more usage in many industries over the past decade. However, the study of creep behavior of thermoplastic composites is not well understood. In this research, Graphite/PEEK thermoplastic composite material was used to develop the orthotropic creep compliance matrix (S(sub ij)(t,o)) and to investigate the long-term creep response. Short-term experiments were conducted to study feasibility of accelerated characterization (TSSP) of creep response for off-axis laminae. The fiber orientations studies for creep tests were 10, 15, 30, 45, 60, 75, and 90 degrees. Based on the short-term creep data of off-axis laminae, the time-dependent orthotropic constitutive law was established to model the non-linear viscoelastic behavior. Results of this research indicate that: (1) The accelerated characterization procedure could be performed using elevated stresses, and the Findley equation represented experimental creep data very accurately. (2) Excellent agreement was found between the experimental results and the predicted results based on the time-dependent orthotropic constitutive law for Graphite/PEEK thermoplastic composite. (3) In comparison with the shifted result from the master curve, the time dependent orthotropic constitutive theory could be more easily used to predict the long-term creep response for any stress level and fiber angle orientation. MODIFIED CARBON FOR IMPROVED CORROSION RESISTANCE Patent Application
Alan S. Edelstein, inventor (to Navy), Richard K. Everett, inventor (to Navy), Patricia Tzaskoma, inventor (to Navy), and Benji Maruyama, inventor (to Navy) 15 Jan. 1993 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D015741; US-Patent-Appl-SN-004002; Navy-Case-74104) Avail: CASI HC A03

The present invention relates to reinforced composites and more particularly to composites reinforced by carbon or graphite that has been

treated to reduce corrosion between the reinforcement material and adjacent metals. Graphite or carbon particles with a graphitic skin are intercalculated with a compound including an oxidized form of a metal and then reduced in a hydrogen atmosphere. This process reduces the driving force for the galvanic reaction between the particles and active metals in aqueous environments. The particles may be present as a reinforcement for a metal matrix (e.g., graphite/aluminum metal matrix composites) or as a reinforcement for a non-metallic material (e.g., graphite/polyimide, graphite/polyester or graphite/cyanate composites). In the latter case, the composite is adjacent to a metal in a structure. By way of example, the graphite or carbon particle may be a fiber, the metal subject to attack may be aluminum or magnesium, and the intercalation compound may be NiCl2. DTIC

EXPERIMENTAL AND ANALYTICAL ANALYSIS OF THE RESPONSE OF A SMART BEAM TO RATE FEEDBACK M.S. Thesis

Terance J. Hoffman Jun. 1993 139 p

(AD-A266544; AFIT/GA/ENY/93J-01) Avail: CASI HC A07/MF A02

A smart beam with embedded sensors and actuators was analyzed and tested. The smart beam studied was constructed from graphite and epoxy with piezoceramic actuators and NiTiNOL sensors embedded. It was mounted vertically and subjected to transverse dynamic loading at the free end. Analytic expressions for the open loop and closed loop response (using strain rate feedback control) of the beam (including internal damping) to external forcing were derived in detail. Experimental testing of the beam, verified the accuracy of the predicted open loop response. DTIC

MODELLING OF THE TEMPERATURE DISTRIBUTION IN A COPPER ROLL FOR THE DESIGN OF A SYSTEM OF COOLED ROLLS ADAPTED TO VERTICAL STRIP CASTING [MODELISATION DE LA DISTRIBUTION DE TEMPERATURE DANS UN ROULEAU DE CUIVRE POUR LA CONCEPTION D'UN SYSTEME DE ROULEAUX REFROIDIS ADAPTE A LA COULEE EN BANDE VERTICALE]

S. Turenne and M.-C. Heuzey Dec. 1992 28 p In FRENCH

(IMI-93RT-21200-1436-G; CNR-35325; CTN-93-60763) Avail: CASI HC A03/MF A01

In vertical strip casting of metal matrix composites, it is proposed to control the process with the help of a strategy yet to be defined. This strategy will be based on the acquisition of velocity signals from the rolls, on the load between the rolls, on the displacement of the mobile roll, and the temperatures at different locations. To facilitate control and the attaining of a steady state regime, it is necessary to design a cooling system for the rolls. A model was developed with the objective of evaluating the performance of such a system taking into account certain constraints. The rolls consist of a copper ring 2.54 cm thick in contact with a stainless steel core having cooling channels on its surface. All the model calculations are performed taking into consideration the A356 aluminum alloy used, whose lower melting point compared to the copper rolls imposes the object of limiting the temperature at the interface between the copper ring and the core. A polar coordinate system is used to model the two-dimensional geometry of the ring, employing a system of finite difference equations in which the temperature is determined at each node simultaneously. Results are presented which allow illustration of the temperature distribution in the copper ring over time. A FORTRAN program listing for calculating the temperature distribution is appended. CISTI

THERMAL SHOCK RESISTANCE OF CERAMIC MATRIX COMPOSITES Final Report

D. M. Carper and H. F. Nied (General Electric Co., Schenectady, NY.) Aug. 1993 50 p

(Contract NAS3-25640; RTOP 510-01-50)

(NASA-CR-189136; E-8070; NAS 1.26:189136) Avail: CASI HC A03/MF A01

The experimental and analytical investigation of the thermal shock phenomena in ceramic matrix composites is detailed. The composite systems examined were oxide-based, consisting of an aluminosilicate matrix with either polycrystalline aluminosilicate or single crystal alumina fiber reinforcement. The program was divided into three technical tasks; baseline mechanical properties, thermal shock modeling, and thermal shock testing. The analytical investigation focused on the development of simple expressions for transient thermal stresses induced during thermal shock. The effect of various material parameters, including thermal conductivity, elastic modulus, and thermal expansion, were examined analytically for their effect on thermal shock performance. Using a simple maximum stress criteria for each constituent, it was observed that fiber fracture would occur only at the most extreme thermal shock conditions and that matrix fracture, splitting parallel to the reinforcing fiber, was to be expected for most practical cases. Thermal shock resistance for the two material systems was determined experimentally by subjecting plates to sudden changes in temperature on one surface while maintaining the opposite surface at a constant temperature. This temperature change was varied in severity (magnitude) and in number of shocks applied to a given sample. The results showed that for the most severe conditions examined that only surface matrix fracture was present with no observable fiber fracture. The impact of this damage on material performance was limited to the matrix dominated properties only. Specifically, compression strength was observed to decrease by as much as 50 percent from the measured baseline. Author (revised)

OPTIMAL SYNTHESIS OF HOT COMPOSITE LAMINATES WITH INTERPHASE LAYERS

Christopher Rabzak (Sverdrup Technology, Inc., Brook Park, OH.), Dimitris A. Saravanos, and Christos C. Chamis Jun. 1993 22 p Presented at the Symposium on Functionally Graded, Advanced Composite Materials, Charlottesville, VA, 6-9 Jun. 1993; sponsored by SES, ASME and ASCE

(RTOP 510-01-50)

(NASA-TM-106326; E-8081; NAS 1.15:106326) Avail: CASI HC A03/MF A01

A method for the optimal grading of a single interphase layer in metal matrix composite laminates for the minimization of residual stresses is described. The capability to simultaneously tailor some fabrication parameters is also incorporated. Applications for unidirectional, cross-ply and

quasi-isotropic Graphite/Copper laminates are investigated to assess the potential of interphase layer in reducing matrix residual stresses in various laminate configurations. Simultaneous optimization of interphase and fabrication characteristics appears to be more effective in decreasing residual stresses. The results also indicate that the interphase layer is more effective in lowering residual stresses in unidirectional composites and selectively within individual plies of a laminate. Embedded interphase layers in all the plies did not produce a significant global reduction in residual stresses.

GRAPHITE FIBER TEXTILE PREFORM/COPPER MATRIX COMPOSITES Semiannual Progress Report No. 1, 1 Jan. - 30 Jun. 1993
G. J. Filatovs 1993 8 p
(Grant NAG3-1432)
(NASA-CR-193797; NAS 1.26:193797) Avail: CASI HC A02/MF A01

This project has the objective of exploring the use of graphite fiber textile preform/copper matrix composites in spacecraft heat transmitting and radiating components. The preforms are to be fabricated by braiding of tows and when infiltrated with copper will result in a 3-D reinforced, near net shape composite with improved specific properties such as lower density and higher stiffness. It is anticipated that the use of textile technology will result in a more robust preform and consequently better final composite; it is hard to anticipate what performance tradeoffs will result, and these will be explored through testing and characterization. CMAPP (Composite Material Properties Prediction) is a menu-driven composite material analysis computer program capable of generating effective material properties for particulate, continuous fiber, and platelet composites. Constituent material properties can also be generated from composite properties. A collection of eight micromechanical material models has been incorporated into the CMAPP model library. A hierarchical arrangement of menus is used to guide the user through the process of defining various material parameters, entering all necessary material data, and storing or displaying the results. CMAPP will not only perform a single analysis, but will also perform analyses for a range of volume fractions. The latter option gives the user the ability to investigate the effect that a volume fraction change has on any desired material property. The program structure of CMAPP is described along with the various menus and menu options contained in the program. Data input and ouput options are noted, and the types of material models available in the program library are reviewed. Author (CISTI)

MEASUREMENT OF STRAIN IN INDIVIDUAL PHASES OF COMPOSITES BEFORE, DURING, AND AFTER MECHANICAL LOADING
J. A. Goldstone, M. A.M. Bourke, Ning Shi, A. C. Lawson, and J. E. Allison (Ford Motor Co., Dearborn, MI.) 1993 10 p Presented at the 12th International Collaboration of Advanced Neutron Sources Meeting (ICANS), Abingdon, England, 24-28 May 1993
(Contract W-7405-eng-36)
(DE93-014585; LA-UR-93-1711; CONF-9305177-5) Avail: CASI HC A02/MF A01

At LANSCE, we have measured residual strains in a variety of metal-matrix systems using the Neutron Powder Diffractometer (NPD). In 1992, we developed a compact stress rig for in-situ strain measurement during applied loading. Comparison of experimental measurements made with the stress rig on aluminum titanium carbide with numerical predictions showed the importance of including initial thermal residual strains in the models. In Al/TiC, normal to the loading direction, the increase in the average matrix and reinforcement lattice strains was in a 'zigzag' manner. Finite element modeling indicated that this resulted from residual strains induced during cooling from fabrication temperatures. Data and modeling are presented.

Failure initiates in local regions of a material microstructure which are either especially weak, or which carry an especially large field. The size and location of these weak or 'hotspots' depends on the microstructure and is especially sensitive to microstructural disorder. Using model random microstructures, we have developed analytic and numerical tools to predict where failure initiates, its initiation field, and how it propagates from the initiation sites. We have found it useful to divide the failure process into a nucleation stage, in which damage occurs quite randomly throughout the material, a localisation stage, where a critical crack nucleates, and a catastrophic failure stage during which an unstable crack propagates through the material. Results are being compared with experiments on: Highly porous materials (porous glass and porous gold); dielectric breakdown of metal loaded insulators (e.g. aluminum in poly-ethyelene) and; the critical current of superconductors containing cracks (Nb and Nb3Ge). This report summarizes our efforts in these areas. DOE

THE STRUCTURE AND MECHANICAL PROPERTIES OF Ru-Cu AND Ru-Ti NANOLAYER COMPOSITES
H. Kung, M. Nastasi, T. R. Jervis, K. Hubbard, T. E. Mitchell, R. M. Messner (Minnesota Mining and Mfg. Co., Saint Paul.), and J. D. Embury (McMaster Univ., Hamilton, Ontario.) 1993 7 p Presented at the Spring Meeting of the MRS, San Francisco, CA, 12-16 Apr. 1993
(Contract W-7405-eng-36)
(DE93-014453; LA-UR-93-1927; CONF-930405-15) Avail: CASI HC A02/MF A01

Multilayers of Ru-Cu and Ru-Ti were prepared by electron beam evaporation technique. One set of composites has Ru thickness varying from 250 to 2500 Angstroms alternating with Cu or Ti of 15 Angstroms. The other set has 250 Angstroms of Ru and the Cu or Ti layer varies between 15 and 200 Angstroms. Nanoindentation measurements show that there is no significant change in hardness as either Ru or Cu/Ti thickness varies. However, the Ru-Cu multilayer has twice the hardness of the Ru-Ti system. The strengthening mechanism proposed by Koehler predicts that Ru-Ti composites would have a higher strength than Ru-Cu due to larger modulus difference between Ru and Ti. Discrepancy between prediction and experiment suggests that other strengthening mechanism(s) may be operating. Two models based on a 'shear' mechanism are proposed to explain the differences observed between these two systems. Effects of these mechanisms in controlling the deformation process in nanolayer composites are discussed. DOE

SMALL-ANGLE SCATTERING, CONTRAST VARIATION AND THE STUDY OF COMPLEX COMPOSITE MATERIALS: A STUDY OF THE STRUCTURE OF CARBON BLACK
R. P. Hjelm, Jr., P. A. Seeger, and W. A. Wampler (Sid Richardson Carbon Co., Forth Worth, TX.) 1993 19 p Presented at the American Chemical Society Meeting on Rubber Chemistry and Technology, Denver, CO, 18-22 May 1993
(Contract W-7405-eng-36)
(DE93-012707; LA-UR-93-1657; CONF-9305185-1) Avail: CASI HC A03/MF A01

Detailed studies are presented on the structure and aggregation of an experimental high surface area carbon black (HSA) using small-angle neutron scattering and the method of contrast variation. We find that the approximately 27 nm HSA particles form small, linear aggregates of average aggregation number 5 when suspended in cyclohexane. There is considerable density fluctuation in the interior of these particles with the denser regions being toward the outer part of the spherically-averaged structure. This information would not have been obtained from studies of carbon black without solvent. The results will be applied to similar scattering studies on solvent-swollen bound rubber gels made from HSA-polyisoprene. These result show, however, that the strong internal fluctuations of the carbon black will limit the information that can be obtained on the structure and conformation of the elastomer in the gel. There are additional limitation from compositional heterogeneity of the sample. DOE

Presentations were made at two national conferences and one workshop. A paper titled 'Enhanced Direct Stiffness Method for Finite Element Analysis of Textile Composites' was presented at the 1992 ASME winter annual meeting in November 1992. A paper titled 'Global/Local Finite Element Analysis for Textile Composites' was presented at the 33rd SDM conference in April 1993. A paper titled 'Boundary Effects in Textile Composites' was presented at a workshop sponsored by NASA Langley Research Center in July, 1993. This paper was also presented at the Second U.S. National Congress on Computational Mechanics in August 1993. A copy of the first paper was included in last year's report. Copies of papers related to the other two talks are included. Details of the research can be found in the papers and theses. While we are encouraged by the results to date, our studies indicate that the current technique for interfacing of global and local models is not as accurate as we had hoped. The current technique involves exact displacement constraints. Because of the crudeness of the global model, this interfacing technique results in significant artifacts in the stress distributions near the global/local boundary. Of course, one could just include a larger region in the local model if there are sufficient computer resources. A high priority this year will be improving the global/local interfacing by using variations of mixed boundary constraints. This will result in some local violation of compatibility, but it might reduce the artifacts near the boundary. A variety of computer programs were developed. The primary programs will be documented during the third year and submitted to COSMIC. Author (revised)

ELASTIC-PLASTIC FINITE ELEMENT ANALYSES OF AN UNIDIRECTIONAL, 9 VOL PERCENT TUNGSTEN FIBER REINFORCED COPPER MATRIX COMPOSITE
Jose G. Sanfeliz Sep. 1993 21 p Original contains color illustrations
(RTOP 510-01-50)
(NASA-TM-106304; E-8045; NAS 1.15:106304) Avail: CASI HC A03/MF A01; 7 functional color pages

Micromechanical modeling via elastic-plastic finite element analyses were performed to investigate the effects that the residual stresses and the degree of matrix work hardening (i.e., cold-worked, annealed) have upon the behavior of a 9 vol percent, unidirectional W/Cu composite, undergoing tensile loading. The inclusion of the residual stress-containing state as well as the simulated matrix material conditions proved to be significant since the Cu matrix material exhibited plastic deformation, which affected the subsequent tensile response of the composite system. The stresses generated during cooldown to room temperature from the manufacturing temperature were more of a factor on the annealed-matrix composite, since they induced the softened matrix to plastically flow. This event limited the total load-carrying capacity of this matrix-dominated, ductile-ductile type material system. Plastic deformation of the hardened-matrix composite during the thermal cooldown stage was not considerable, therefore, the composite was able to sustain a higher stress before showing any appreciable matrix plasticity. The predicted room temperature, stress-strain response, and deformation stages under both material conditions represented upper and lower bounds characteristic of the composite's tensile behavior. The initial deformation stage for the hardened material condition showed negligible matrix plastic deformation while for the annealed state, its initial deformation stage showed extensive matrix plasticity. Both material conditions exhibited a final deformation stage where the fiber and matrix were straining plastically. The predicted stress-strain results were compared to the experimental, room temperature, tensile stress-strain curve generated from this particular composite system. The analyses indicated that the actual thermal-mechanical state of the composite's Cu matrix, represented by the experimental data, followed the annealed material condition. Author (revised)

A STUDY OF FIBER VOLUME FRACTION EFFECTS IN NOTCHED UNIDIRECTIONAL SCS-6/Ti-15V-3Cr-3Al-3Sn COMPOSITE Ph.D. Thesis Final Report
Steven J. Covey Sep. 1993 226 p
(Grant NGT-40016; RTOP 510-01-50)
(NASA-CR-191165; E-8116; NAS 1.26:191165) Avail: CASI HC A11/MF A03

Notched unidirectional SCS-6/Ti-15-3 composite of three different fiber volume fractions (vf = 0.15, 0.37, and 0.41) was investigated for various room temperature microstructural and material properties including: fatigue crack initiation, fatigue crack growth, and fracture toughness. While the matrix hardness is similar for all fiber volume fractions, the fiber/matrix interfacial shear strength and matrix residual stress increases with fiber volume fraction. The composite fatigue crack initiation stress is shown to be matrix controlled and occurs when the net maximum matrix stress approaches the endurance limit stress of the matrix. A model is presented which includes residual stresses and presents the composite initiation stress

as a function of fiber volume fraction. This model predicts a maximum composite initiation stress at vf approximately 0.15 which agrees with the experimental data. The applied composite stress levels were increased as necessary for continued crack growth. The applied Delta(K) values at crack arrest increase with fiber volume fraction by an amount better approximated using an energy based formulation rather than when scaled linear with modulus. After crack arrest, the crack growth rate exponents for vf37 and vf41 were much lower and toughness much higher, when compared to the unreinforced matrix, because of the bridged region which parades with the propagating fatigue crack. However, the vf15 material exhibited a higher crack growth rate exponent and lower toughness than the unreinforced matrix because once the bridged fibers nearest the crack mouth broke, the stress redistribution broke all bridged fibers, leaving an unbridged crack. Degraded, unbridged behavior is modeled using the residual stress state in the matrix ahead of the crack tip. Plastic zone sizes were directly measured using a metallographic technique and allow prediction of an effective matrix stress intensity which agrees with the fiber pressure model if residual stresses are considered. The sophisticated macro/micro finite element models of the 0.15 and 0.37 fiber volume fractions presented show good agreement with experimental data and the fiber pressure model when an estimated effective fiber/matrix debond length is used. Dichloroketene, generated by the ultrasound-promoted dechlorination of trichloroacetylchlroide with zinc, has been added to the carbon-carbon double bond of poly (1,1-dimethyl-1-sila-cis-pent-3-ene)(poly-I). The molecular-weight distribution of the adduct polymer in which all of the carbon-carbon double bonds have reacted with dichloroketene, one dimethylsiylene). One hundred percent poly(I-Cl2C=C=O), has been characterized by bel permeation chromatography. The microstructure of the 100 percent poly(I-Cl2C=C=O) has been elucidated by H-1, C-13, and Si-29 nuclear magnetic resonance as well as by infrared spectroscopy. Similarly, a series of random copolymers have been prepared in which only some of the carbon-carbon double bonds of poly-I have reacted with dichloroketene. These have been characterized as above. The glass transition teperatures (T sub g) of these copolymers, as well as that of 100 percent poly(I-Cl2C=C=O), have been determined by differential scanning calorimetry. The T sub g values are found to increase linearly with the percentag of the carbon-carbon double bonds of poly-I that have reacted with dichloroketene. Author

The state of damage of a composite is evaluated using the deferred acoustic emission technique. Deferred acoustic emission is the name given to the acoustic activity observed, under a constant charge, in material composites and carbon/matrix epoxy composite fibers. The mechanical behavior of the composites under constant charge is observed in order to model the phenomena which control deferred acoustic emission. The deferred acoustic emission is linked to the establishment of damage in the composite. Under a constant charge, the damage is governed by the evolution of the deformation of the composite linked to the rheology of the constitents. The method enables the evolution of the events to be monitored and the transition from a diffuse damage phase to a localized damage phase to be identified. ESA

THERMOMECHANICAL AND ISOTHERMAL FATIGUE BEHAVIOR OF A (90)SUB 8 TITANIUM MATRIX COMPOSITE Final Report

Michael G. Castelli Oct. 1993 14 p Proposed for presentation at the Eighth Technical Conference on Composite Materials, Cleveland, OH, 19-21 Oct. 1993; sponsored by the American Society for Composites

(Contract NAS3-25266; RTOP 510-01-50)

(NASA-CR-191196; E-8156; NAS 1.26:191196) Avail: CASI HC A03/MF A01

An experimental investigation was conducted to analyze the fatigue damage mechanisms operative in a 35 fiber volume percent (90 deg) titanium matrix composite (TMC) under 427 C isothermal and thermomechanical loading conditions. The thermomechanical fatigue (TMF) tests were performed with a temperature cycle from 200 to 427 C under closely controlled conditions to define both the deformation and fatigue life behavior. Degradation of the TMC's isothermal elastic moduli and coefficient of thermal expansion were monitored throughout the TMF tests. The results indicated TMF life trends which contrasted those established in a comparable (0 deg) system, as TMF loading of the (90 deg) TMC was not found to be 'life-limiting' in comparison to maximum temperature isothermal conditions. In-phase lives were very similar to those established under 427 C isothermal conditions. High stress isothermal fatigue at 427 C produced increased strain ratchetting and stiffness degradation relative to TMF conditions. Out-of-phase loadings produced TMF lives approximately an order of magnitude greater than the lives determined under isothermal and in-phase conditions. Extensive fractography and metallography were also performed. Two key issues were identified and appeared to dominate the fatigue damage and life of the (90 deg) TMC, namely, the weak fiber/matrix interface and environmental attack of the fiber/matrix interface via the exposed (90 deg) fiber ends. THERMOELASTIC RESPONSE OF METAL MATRIX COMPOSITES WITH LARGE-DIAMETER FIBERS SUBJECTED TO THERMAL GRADIENTS

Jacob Aboudi (Virginia Univ., Charlottesville.), Marek-Jerzy Pindera (Virginia Univ., Charlottesville.), and Steven M. Arnold Oct. 1993 76 p

(RTOP 510-01-50)

(NASA-TM-106344; E-8114; NAS 1.15:106344) Avail: CASI HC A05/MF A01

A new micromechanical theory is presented for the response of heterogeneous metal matrix composites subjected to thermal gradients. In contrast to existing micromechanical theories that utilize classical homogenization schemes in the course of calculating microscopic and macroscopic field quantities, in the present approach the actual microstructural details are explicitly coupled with the macrostructure of the composite. Examples are offered that illustrate limitations of the classical homogenization approach in predicting the response of thin-walled metal matrix composites with large-diameter fibers when subjected to thermal gradients. These examples include composites with a finite number of fibers in the thickness direction that may be uniformly or nonuniformly spaced, thus admitting so-called functionally gradient composites. The results illustrate that the classical approach of decoupling micromechanical and macromechanical analyses in the presence of a finite number of large-diameter fibers, finite dimensions of the composite, and temperature gradient may produce excessively conservative estimates for macroscopic field quantities, while both underestimating and overestimating the local fluctuations of the microscopic quantities in different regions of the composite. Also demonstrated is the usefulness of the present approach in generating favorable stress distributions in the presence of thermal gradients by appropriately tailoring the internal microstructure details of the composite. When an object is subjected to the flow of combustion gas at a different temperature, the thermal responses of the object and the surrounding gas become coupled. The ability to model this interaction is of primary interest in the design of components which must withstand fire environments. One approach is to decouple the problem and treat the incident flux on the surface of the object as being emitted from a black-body at an approximate gas temperature. By neglecting the presence of the participating media, this technique overpredicts the heat fluxes initially acting on the object surface. The main goal of this work is to quantify the differences inherent in treating the combustion media as a blackbody as opposed to a gray gas. This objective is accomplished by solving the coupled participating media radiation and conduction heat transfer problem. A transient conduction analysis of a vertical flat plate was performed using a gray gas model to provide a radiation boundary condition. A 1-D finite difference algorithm was used to solve the conduction problem. The results are presented in terms of nondimensional parameters and include both average and local heat fluxes as a function of time. Early in the transient, a reduction in net heat fluxes of up to 65% was observed for the gray gas results as compared to the blackbody cases. This reduction in the initial net heat flux results in lower surface temperatures for the gray gas case. Due to the initially reduced surface temperatures, the gray gas net heat flux exceeds the net blackbody heat flux with increasing time. For radiation Blot numbers greater than 5, or values of the radiation parameter less than 10(sup -2). the differences inherent in treating the media as a gray gas are negligible and the blackbody assumption is valid. The results clearly indicate the importance of participating media treatment in the modeling of the thermal response of objects in fires and large combustion systems. DOE

The goal of this study is to model the lifetime of different types of seal materials based on results obtained from accelerated experiments. A semi-mechanistic approach was taken. Thermal aging data were taken from the literature whereas experiments were conducted at Auburn under this contract for selected environments. The seal materials of interest are Silicone 383, Silicone 650, Viton 835, and Viton 747. The relevant conditions include thermal, oxygen, inert gas, vacuum, and gamma radiation. Compression set data available from NASA were used to examine the thermal effect. Experiments were conducted at Auburn University and at NASA to isolate the role of thermal, oxygen, inert gas, vacuum, gamma irradiation, and proton irradiation. A simple discrete stress relaxation method was developed to determine the relaxation response of the elastomers. Dynamic mechanical thermal analysis was also used to characterize the mechanical response of the specimens. These provide a more meaningful correlation between mechanisms and degradation. PHOTOCATALYSIS FOR THE TREATMENT OF WASTE WATER: APPLICATIONS INVOLVING THE REMOVAL OF METALS
M. R. Prairie and B. M. Stange 1993 7 p Presented at the National Conference and Exposition on Heat Transfer, Atlanta, GA, 8-11 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-011669; SAND-93-0023C; CONF-930830-14) Avail: CASI HC A02/MF A01

This paper describes laboratory work investigating the applicability of solar-powered photocatalysis for the treatment of water contaminated with heavy metals and organics. It was found that Ag(I), Au(HI), Cr(VI), Hg(H), Pd(H), and PT(IV) are easily treated while Cd(U), Cu(II), and NI(II) are not. The importance of the entire photocatalytic redox cycle is demonstrated by showing that the rates of oxidation (of organics) and reduction (of metals) are intrinsically interrelated. Data are presented showing that photoefficiency decreases as light intensity increases in the range of 0 to 17 suns UV. This result suggests that one-sun systems are more efficient than those using concentrated solar radiation. Preliminary data are reported for three samples of actual waste: (1) gold mining leachate, (2) precious metals mining extract, and (3) photographic waste. In general, actual applications are less effective than predicted using laboratory data for clean systems. DOE

THE IMPORTANCE OF HARD CORE REPULSION IN MODELS OF ACTIVITY COEFFICIENTS IN AQUEOUS ELECTROLYTE SOLUTIONS: ILLUSTRATION IN THE CASE OF HYDRATION THEORY
T. J. Wolery and K. J. Jackson Jul. 1992 5 p Presented at the 7th Water-Rock Interaction Conference, Park City, UT, 9-23 Jul. 1992
(Contract W-7405-eng-48)
(DE93-012476; UCRL-JC-109948; CONF-920761-17) Avail: CASI HC A01/MF A01

Activity coefficients in aqueous electrolyte solutions are primarily affected by two kinds of phenomena. The standard Debye-Huckel equation represents only one of these--the long range electrical interactions. Of nearly equal importance is hard core (HC) repulsion, which is not electrical in nature. To a first-order approximation, HC repulsive effects are independent of the ionic strength depending instead on the sum of the solute molalities (Sigma(m)). Adding a term for HC repulsion to the standard Debye-Huckel model produces what we call a hybrid two-term model. In a previous work, we proposed a new method for making hydration corrections to the standard Debye-Huckel model. In the present work, we examine the effect of extending this model to include hard core repulsion. Although the activity coefficients of 1:1 electrolytes can be fit quite well by the model without a HC term the inclusion of such a term is critical to success in fitting the data for 2:1 and other higher-order electrolytes. An eXplosive CHEMical kinetics code (XCHEM) was developed to solve the reactive diffusion equations associated with thermal ignition of energetic material. This method-of-lines code uses stiff numerical methods and adaptive meshing. Solution accuracy is maintained between multilayered materials consisting of blends of reactive components and/or inert materials. Phase change and variable properties are included in one-dimensional slab, cylindrical, and spherical geometries. Temperature-dependent thermal properties were incorporated, and modification of thermal conductivities to

include decomposition effects are estimated using solid/gas volume fractions determined by species fractions. Gas transport properties are also included. Time varying temperature, heat flux, convective and thermal radiation boundary conditions, and layer to layer contact resistances are also implemented. The global kinetic mechanism, developed at Lawrence Livermore National Laboratory (LLNL), used to fit One-Dimensional Time to eXplosion (ODTX) data for the conventional energetic materials (HMX, RDX, TNT, and TATB) are presented as sample calculations representative of multistep chemistry. Calculated and measured ignition times for explosive mixtures of Comp B (RDX/TNT), Octol, (HMX/TNT), PBX 9404 (HMX/NC), and RX-26-AF (HMX/TATB) are compared. Geometry and size effects are accurately modeled, and calculations are compared to experiments with time varying boundary conditions. Finally, XCHEM calculations of initiation of an AN/oil/water emulsion, resistively heated, are compared to measurements. DOE

DETERMINATION OF TRACE ELEMENTS IN TRIGLYCINE SULFATE SOLUTIONS Final Technical Report
Shawky H. Tadros 31 Jul. 1993 14 p
(Grant NAG8-204)
(NASA-CR-193481; NAS 1.26:193481) Avail: CASI HC A03/MF A01

Ten elements were divided into 2 groups. The elements in the first group included iron, nickel, chromium, manganese, copper, and gold. The elements in the second group included zinc, cobalt, lead, cadmium, and gold. Five ppm of each element in each group was spiked in a 1 percent triglycine sulfate (TGS) solution. Glycine was removed with 1-naphthyl isocyanate in ether medium. The glycine derivative 1-naphthyl isocyanate glycine was removed by filtration, and the filtrates were analyzed for the different elements. Analysis of these elements was performed by using the 5100 Perkin-Elmer Atomic Absorption Spectrophotometer. The result of these experiments was the observation that there was a decrease in the concentration of chromium and gold, which was interpreted to be due to the chelation of these elements by the derivative 1-naphthyl isocyanate glycine. Further research is needed to determine the concentration of other elements in triglycine sulfate (TGS) solutions. These elements will include lithium, sodium, rubidium, magnesium, calcium, strontium, barium, aluminum, and silicon. These are the most likely elements to be found in the sulfuric acid used in manufacturing the TGS crystal. Moreover, we will extend our research to investigate the structural formula of the violet colored chelated compounds, which had been formed by interaction of the derivative 1-naphthyl isocyanate glycine with the different elements, such as gold, chromium. A COHERENT FLAME MODEL OF PREMIXED TURBULENT COMBUSTION IN A COUNTERFLOW GEOMETRY
A. S. Wu and K. N. C. Bray 26 Jan. 1993 34 p
(CUED/A-THERMO/TR.60) Avail: CASI HC A03/MF A01

Premixed combustion in turbulent counterflowing streams is studied theoretically by adopting a coherent flame model. With this model, a flame surface density Sigma-bar, described by a transport equation, is used to calculate the mean chemical reaction rate related to the distribution of a mean progress variable c-bar. The values of two model constants alpha and beta, connected to flame surface stretch and annihilation, are selected to match numerical solutions with experiments at different nozzle exit conditions giving various values of the mean progress variables at the stagnation point c-bar(0). It is found that two different regions exist in the counterflow field: an outer region, far from the stagnation point and without chemical reaction, and an inner sublayer, which is close to the stagnation point, which experiences a large bulk strain rate and is located in the combustion zone. In order to provide an appropriate theoretical description of the experimental conditions, the inner region is allowed to have a finite thickness, thus imposing a finite displacement on the outer solution, due to thermal expansion in the sublayer. A composite solution is obtained by matching the boundary conditions of the inner and outer solutions at the cold flame edge. The effective mean bulk strain rate is increased slightly by the displacement effect. Theoretical predictions are found to be in good agreement with the experimental data. Author (revised)

NOVEL OXYGEN ATOM SOURCE FOR MATERIAL DEGRADATION STUDIES Final Report, 1 Mar. 1986 - 1 Sep. 1988
R. H. Krech and G. E. Caledonia Oct. 1988 104 p
(Contract NAS7-963; SBIR-04.14-9030)
(NASA-CR-191323; NAS 1.26:191323; PSI-1001/TR-871) Avail: CASI HC A06/MF A02

Physical Sciences Inc. (PSI) has developed a high flux pulsed source of energetic (8 km/s) atomic oxygen to bombard specimens in experiments on the aging and degradation of materials in a low earth orbit environment. The proof-of-concept of the PSI approach was demonstrated in a Phase 1 effort. In Phase 2 a large O-atom testing device (FAST-2) has been developed and characterized. Quantitative erosion testing of materials, components, and even small assemblies (such as solar cell arrays) can be performed with this source to determine which materials and/or components are most vulnerable to atomic oxygen degradation. The source is conservatively rated to irradiate a 100 sq cm area sample at greater than 10(exp 17) atoms/s, at a 10 Hz pulse rate. Samples can be exposed to an atomic oxygen fluence equivalent to the on-orbit ram direction exposure levels incident on Shuttle surfaces at 250 km during a week-long mission in a few hours. INFRARED SPECTROSCOPY OF ORGANIC FREE RADICALS RELATED TO COMBUSTION PROCESSES
J. C. Weisshaar 25 Feb. 1993 5 p
(Contract DE-FG02-92ER-14306)
(DE93-017086; DOE/ER-14306/1) Avail: CASI HC A01/MF A01

We will explore a variant of resonant two-photon ionization (R2PI). Development of the IR + UV R2PI experiment is underway. We have used optical R2PI and pulsed field ionization detection to obtain vibrational spectra of the benzyl and phenylsilane cations. In benzyl, we have learned about the vibronic coupling in the mixed 1(sup 2)A(sub 2)-2(sup 2)B(sub 2) system near 450 nm by projecting the mixed states onto the manifold of cation vibrational states. In phenylsilane(sup +), we find that the sixfold

barrier to internal rotation of the silyl group is small (V(sub 6)= +19 /cm. We are beginning to understand the mechanisms of coupling of torsional states with vibrations, overall rotation, and other electronic states, and we are developing a model of internal rotation in aromatic compounds based on Weinhold's natural resonance theory. EXPERIMENTAL AND KINETIC MODELING OF ACID/BASE AND REDOX REACTIONS OVER OXIDE CATALYSTS
1993 38 p
(Contract DE-FG02-84ER-13183)
(DE93-016203; DOE/ER-13183/8) Avail: CASI HC A03/MF A01

The research has involved the following: the characterization of catalyst acidity; D-2 NMR studies of Bronsted acid sites; and kinetic, calorimetric, and spectroscopic studies of methylamine synthesis and related reactions over acid catalysts. The approach of this work was to explore quantitative correlations between factors that control the generation, type, strength, and catalytic properties of acid sites on zeolite catalysts. Microcalorimetry, thermogravimetric analysis, IR spectroscopy, and NMR spectroscopy have provided information about the nature and strength of acid sites in zeolites. This was vital in understanding the catalytic cycles involved in methylamine synthesis and related reactions over zeolite catalysts. DOE

APPLICATION OF SYNCHROTRON RADIATION IN CHEMICAL DYNAMICS
P. Heimann, M. Koike, A. H. Kung, C. Y. Ng, M. G. White, and A. Wodtke May 1993 31 p Presented at the Application of Synchrotron Radiation and Chemical Dynamics Workshop Report, Oakland, CA, 3-5 Feb. 1993
(Contract DE-AC03-76SF-00098)
(DE93-015040; LBL-34131; CONF-9302107-Summ) Avail: CASI HC A03/MF A01

In Oct. 1992 funding was approved to begin construction of a beamline and two end stations to support chemical dynamics experiments at LBL's Advanced Light Source (ALS). This workshop was organized to develop specifications and plans and to select a working team to design and supervise the construction project. Target date for starting the experiments is Jan. 1995. Conclusions of the workshop and representative experiments proposed in earlier workshops to form the basis for beamline plans and end-station designs are summarized in this report. DOE

SURFACE SCIENCE INSTRUMENTATION FOR THE STUDY OF IMPORTANT CATALYTIC AND ELECTROCHEMICAL INTERFACES
1992 4 p
(Contract DE-FG05-90ER-75582)
(DE93-015068; DOE/ER-75582/T1) Avail: CASI HC A01/MF A01

The equipment combines several standard surface science probes (uv photoelectron spectra, thermal desorption, AES) with a state-of-the-art x-ray photoelectron spectrometer and integrates these in a custom design with a dry box and a custom-built electrochemical cell. Since the LEED chamber was remachined, the instrument has been performing satisfactorily. Various studies using the instrument were conducted in cooperation with other groups. Silicon surfaces were studied before and after use as a photoanode in a photoelectrochemical cell. DOE

CHEMICAL REACTIONS IN SCRAMJET ENGINES: REDUCED KINETIC MODELS FOR IGNITION, COMBUSTION AND NOZZLE FLOW [SUKURAMU JETTO NIOKERU KAGAKU HANNOU KANRYAKUKA HANNOUKEI NIYORU KOUSATSU]
Tooru Mitani Nov. 1992 32 p In JAPANESE
(NAL-TR-1184; JTN-93-80506) Avail: CASI HC A03/MF A01

Reduced kinetics for chemical reactions in scramjet engines were investigated. Ignition, combustion in combustors, and reactive flow in nozzles are described using a phase plane for radical concentrations. The effectiveness of radicals introduced to ignite premixtures was studied using analytical solutions representing time histories of three radical concentrations. The contribution of exothermicity to ignition delay and burning rate as well as inhibition caused by H2O were elucidated using simplified asymptotic analysis for H2/O2 systems. New reduced kinetic models for H2 combustion are proposed and compared with other models. Characteristics of ignition and flame-holding in scramjet combustors are discussed using the model derived here. Author (NASDA)

RECENT DEVELOPMENTS IN MULTIPLE-SCATTERING CALCULATIONS OF XAFS AND XANES
J. J. Rehr 1992 5 p Presented at the 7th International Conference on X Ray Absorption Fine Structure, Kobe, Japan, 23-29 Aug. 1992
(Contract DE-FG06-90ER-45415)
(DE93-010999; DOE/ER-45415/6; CONF-9208160-7) Avail: CASI HC A01/MF A01

Curved-wave multiple-scattering (MS) theory provides a unified treatment of XAFS, encompassing both EXAFS and XANES, as well as a formal equivalence between exact treatments and the (MS) expansion carried to all orders. Recent developments in the theory of XAFS are reviewed with an emphasis on progress in curved-wave MS calculations and on understanding the nature of MS contributions in EXAFS and XANES. In particular, a unified ab initio MS treatment of XAFS is discussed based on a scattering matrix formalism which has sufficient speed and accuracy to treat high-order MS in extended systems. Neither low-order MS nor full MS theories are fully satisfactory. Instead, sufficiently high-order MS appears to be necessary for the convergence of both EXAFS and XANES calculations. The approach also gives a MS interpretation of the sigma(*) shape-resonances observed in XANES. It is shown that these peaks result from coherent, high-order MS. A generalization of the Natoli rule correlating the resonance locations with bond length is obtained. DOE

MANY-BODY CORRECTIONS IN XAFS
J. J. Rehr 1992 5 p Presented at the International Workshop on Surface X Ray Absorption Fine Structure, Jaipur, India, Aug. 1992
(Contract DE-FG06-90ER-45415)
(DE93-011002; DOE/ER-45415/9; CONF-9208221-2) Avail: CASI HC A01/MF A01

The importance of many-body effects in the theory of XAFS is reviewed. The dominant effects are inelastic losses. Extrinsic losses refer to inelastic losses in the propagation of the photoelectron and are treated using a complex, energy-dependent self-energy. The real part of the self-energy yields an important energy-dependent shift in the phase of the XAFS oscillations, while the imaginary part contributes to the mean-free-path. Intrinsic losses refer to losses associated with the creation of the core-hole. They give rise to shake-up/shake-off contributions to the absorption spectra. These losses may be calculated in terms of a corehole Green's function.

Interference between these processes leads to dynamical corrections, which are important at low energies. DOE

REDUCTION OF Pu(6) WITH HYDROGEN PEROXIDE: EFFECTS OF PLUTONIUM, PEROXIDE, AND IRON CONCENTRATIONS AND OF REACTION TIME
S. F. Marsh, E. A. Martinez, R. S. Day, and A. E. Nixon Jun. 1993 8 p
(Contract W-7405-eng-36)
(DE93-013598; LA-12554) Avail: CASI HC A02/MF A01 (US Sales Only)

The rate and extent of Pu(6) reduction in 7 M nitric acid were measured as a function of the concentration of plutonium, the relative concentrations of hydrogen peroxide and iron, and the reaction time. Plutonium concentrations of 2, 5, 15, 30, and 50 g/L were evaluated. At each plutonium concentration, the tested mole ratios of H2O2/Pu were 0, 2, 4, and 8, and the mole ratios of Fe/Pu were 0, 0.1, 0.3, and 0.5. Plutonium oxidation states were determined by absorption spectrophotometry before treatment and after reaction periods of 30 min, 2 h, and 6 h. High concentrations of plutonium promote the reduction of Pu(6) by peroxide. Iron hinders the reduction of Pu(6) at low concentrations of plutonium but promotes the reaction at higher plutonium concentrations. Although a significant portion of Pu(6) is often reduced completely to Pu(3) by peroxide in the absence of iron, Pu(3) is reoxidized to Pu(4) in nitric acid when iron is present. DOE

NUMERICAL STUDIES OF SPRAY COMBUSTION IN LIQUID-FUELED ENGINES Ph.D. Thesis
Huan-Min Shang 1992 217 p
Avail: Univ. Microfilms Order No. DA9306600

A non-iterative numerical technique for computing time-dependent spray combustion flows has been developed and the numerical models are equipped with state-of-the-art sophisticated sub-physical models. The method is a fully interacting combination of Eulerian fluid and Lagrangian particle calculations. The interaction calculations between the two phases are formulated on a pressure-velocity coupling procedure based on the operator-splitting technique (PISO). This procedure eliminates the global iterations required in conventional Particle-Source-In-Cell (PSIC) procedure and, hence, is efficient for transient calculations. Particle motion is described on a Lagrangian coordinate for the present separated flow models. Particle dispersion by turbulent fluctuations is modeled by allowing particles to interact with a succession of eddies using a random-walk or Monte Carlo method and the related flow turbulence quantities are modeled through a two-equation k-Epsilon model. Parcel PDF model is used to improve computational efficiency of particle turbulent dispersion. Poly-disperse is achieved by using size distribution function through Monte Carlo technique or generated by breakup model. Droplet evaporation and heat transfer are calculated using Frossling correlation and Ranz-Marshall correlation respectively. The turbulence modulation effect caused by the two-way turbulence-particle interaction is also modeled based on the stochastic framework. Accurate calculation of droplet mass and heat transfer is achieved by automatic reductions in the timestep when the exchange rate becomes large. The variable thermophysical properties are obtained from JANAF data bank. A turbulent diffusion flame and single step chemical reaction model are used for spray combustion. Dense spray effects are taken into account by droplet breakup and collision models. Two breakup models including a Taylor analogy breakup (TAB) model and a wave instability model are incorporated and compared. The incorporated collision model stochastically calculates the outcome of every collision, either coalescence or grazing collision. Several particle dispersions in homogeneous and nearly-homogeneous turbulent flows are studied to calibrate the stochastic method for particle-turbulence interactions, and to evaluate the present parcel PDF model. The computations were performed for the solid particle dispersion in a nearly-homogeneous turbulent flow and a particle laden round jet within homogeneous turbulence. Non-evaporating transient and steady solid-cone sprays are used to test the models of dense spray effects including droplet breakup and collision/coalescence. Turbulence modulation effect and the efficiency of parcel PDF model for a dense spray case are tested at a steady solid-cone spray. A transient hollow cone spray presents the complicated two-phase interactions. Transient evaporating and burning sprays incorporating droplet breakup model, evaporation model and eddy-breakup combustion model demonstrate the sophisticated structures of such polydispersed spray combustion. The predictions show reasonable agreements with available experimental results and indicate that the present methodologies are accurate and efficient for simulation of spray combustion. Dissert. Abstr.

REVIEW OF TEST METHODS FOR MATERIAL FLAMMABILITY
J. J. Conn and G. A. Grant Mar. 1991 79 p
(DSIS-93-00480; CTN-93-60748) Avail: CASI HC A03

A general review of flammability and thermal protection is provided. The emphasis of this review is on the use of the many tests used to examine various aspects of flammability and on the limitations associated with the different methodologies. The study was done so that more refined test methods may be employed to evaluate the protection afforded under defined hazard conditions with varying fluences and fluxes of thermal radiation. Special attention is given to test methodologies employed to evaluate military equipment and materials to ascertain if the present methods are relevant to the actual hazard. The nature of skin burn injury is noted, factors involved in the determination of thermal protective performance are noted, and the characteristics of the sensors and the heat sources used in the various tests are detailed. SURFACTANT STUDIES FOR BENCH-SCALE OPERATION Quarterly Technical Progress Report No. 2, 1 Oct. - 31 Dec. 1992
Gregory S. Hickey and Pramod K. Sharma 1 Mar. 1993 21 p
(Contract NAS7-918)
(NASA-CR-194511; JPL-Publ-93-7; NAS 1.26:194511) Avail: CASI HC A03/MF A01

A phase 2 study has been initiated to investigate surfactant-assisted coal liquefaction, with the objective of quantifying the enhancement in liquid yields and product quality. This report covers the second quarter of work. The major accomplishments were: completion of coal liquefaction autoclave reactor runs with Illinois number 6 coal at processing temperatures of 300, 325, and 350 C, and pressures of 1800 psig; analysis of the filter cake and the filtrate obtained from the treated slurry in each run; and correlation of the coal conversions and the liquid yield quality to the surfactant concentration. An increase in coal conversions and upgrading of the liquid product quality due to surfactant addition was observed for all runs. Author (revised)

PARTIAL ANALYSIS OF LDEF EXPERIMENT A-0114 Final Report, 20 May 1985 - 19 Nov. 1991
John C. Gregory 1991 34 p
(Contract NAS8-36645)
(NASA-CR-193826; NAS 1.26:193826) Avail: CASI HC A03/MF A01

During the contract period, work concentrated on four main components. Data from the UAH silver pin hole camera was analyzed for determination of the mean Long Duration Exposure Facility (LDEF) satellite attitude and stability in orbit, to include pitch and yaw. Chemical testing performed on the AO-114 hot plate determined the form and locus of absorption of cosmogenic beryllium-7. Reaction rates of atomic oxygen with Kapton and other polymeric solids integrated over the whole LDEF orbital lifetime were analyzed. These rates were compared with the JSC estimated values for Space Station exposures. Metal and polymer films exposed on A0114 (C-9 and C-3 plates) were also analyzed. Author (revised)

MODELING AND SIMULATION OF TRANSPORT AND COMBUSTION PHENOMENA IN A SUPERSONIC MIXING LAYER Ph.D. Thesis - Ecole Centrale de Paris [MODELISATION ET SIMULATION DES PHENOMENES DE TRANSPORT ET COMBUSTION DANS UNE COUCHE DE MELANGE SUPERSONIQUE]
Patrick Vuillermoz Nov. 1992 267 p In FRENCH Sponsored by SEP, Vernon, France, and Ministere de la Recherche et de l'Espace, Paris, France Original contains color illustrations
(ONERA-NT-1992-11; ETN-93-93970) Avail: CASI HC A12/MF A03

Numerical simulation and modeling of supersonic mixing layers are discussed. The theoretical background of compressible turbulence from a hydrodynamic point of view (Reynolds stress) as well as diffusive (turbulent mixing) and reactive turbulent combustion points of view are studied. The main experimental results and numerical studies in supersonic mixing are reviewed and the question of direct numerical simulation of turbulent mixing in nonsteady two dimensional and three dimensional mixing layers is addressed. These simulations are in agreement with experimental observations concerning the mixing regimes, the small scale structure in thin layers, and the effects of the convective Mach number. Before examining the effects of chemical reactions, the basic problem of one dimensional strained or unstrained diffusion flames are discussed as a benchmark for kinetics models and for the numerical codes. The theoretical analysis is carried out through a Crocco transformation that points out the inner structure of diffusion flames. These results were used for further numerical simulation of supersonic reactive mixing layers. The effect of the Damkoehler number in combustion regimes is studied. The simulations generated with reduced and with full chemistry are compared. A mixing enhancement technique is examined with simulations on a passively parallel computer. The results of the direct numerical simulations are used for modeling turbulent mixing and accounting for compressibility effects. ESA

HYDROGEN PEROXIDE SAFETY ISSUES
W. V. Conner 14 Apr. 1993 16 p
(Contract DE-AC34-90DP-62349)
(DE93-013895; RFP-4599) Avail: CASI HC A03/MF A01

A literature survey was conducted to review the safety issues involved in handling hydrogen peroxide solutions. Most of the information found in the literature is not directly applicable to conditions at the Rocky Flats Plant, but one report describes experimental work conducted previously at Rocky Flats to determine decomposition reaction-rate constants for hydrogen peroxide solutions. Data from this report were used to calculate decomposition half-life times for hydrogen peroxide in solutions containing several decomposition catalysts. The information developed from this survey indicates that hydrogen peroxide will undergo both homogeneous and heterogeneous decomposition. The rate of decomposition is affected by temperature and the presence of catalytic agents. Decomposition of hydrogen peroxide is catalyzed by alkalies, strong acids, platinum group and transition metals, and dissolved salts of transition metals. Depending upon conditions, the consequence of a hydrogen peroxide decomposition can range from slow evolution of oxygen gas to a vapor, phase detonation of hydrogen peroxide vapors. DOE

LIQUID AND GAS EVANESCENT WAVE SPECTROSCOPY VIA TUNABLE LASERS AND SILVER HALIDE FIBERS M.S. Thesis
Avi Messica Jun. 1990 144 p In HEBREW
(ITN-93-85226) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

Attenuated total reflection (ATR) spectroscopy depends on the existence of an evanescent, energy-non-transmitting field outside a totally internally reflecting waveguide. When the waveguide is immersed in a powder or liquid, attenuated total reflection (ATR) takes place at wavelengths corresponding to the energy bands of the powder or liquid. In ATR spectroscopy, the commonly used Fourier Transform Infrared Spectrometer (FTIR) can be replaced as an infrared (IR) source with a tunable IR laser, and expensive ZnSe or Ge prisms can be replaced as ATR elements with IR-transmitting fibers, which are inexpensive and easier to handle. In the present work, the ATR elements were AgCl(x)Br(1-x) fibers and semiconducting lead salts and CO2 lasers were used as tunable IR sources. Two different optical arrangements were used to demonstrate the practicability of recording ATR gas spectra. A three-dimensional theoretical model was developed to describe the ATR mechanism and the system was analysed. Potential applications of ATR spectroscopy of gases and liquids include measurements of solvent-solute concentrations and gas pressures, and control or study of chemical processes. The theoretical model can aid in designing the laser/fiber optical setup including the optimization of several controlled parameters. ISA

IMMISCIBLE PHASE INCORPORATION DURING DIRECTIONAL SOLIDIFICATION OF HYPERMONOTECTICS Final Report
J. Barry Andrews and Roger A. Merrick Aug. 1993 64 p
(Grant NAG8-768)
(NASA-CR-194412; NAS 1.26:194412) Avail: CASI HC A04/MF A01

Solidification processes in immiscible samples were investigated by directly observing the events taking place at the solid-liquid interface during directional solidification. Visualization of these events was made possible through the use of a transparent metal analog system and a temperature gradient stage assembly fitted to an optical microscope. The immiscible transparent analog system utilized was the succinonitrile-glycerol system. This system has been shown to exhibit the same morphological transitions as observed in metallic alloys of monotectic composition. Both monotectic and hypermonotectic composition samples were directionally solidified in order to gain an improved understanding of the manner in which the excess hypermonotectic liquid is incorporated into the solidifying structure. The processing conditions utilized prevented sedimentation of the excess hypermonotectic liquid by directionally solidifying the samples in very thin (13 microns), horizontally oriented cells. High thermal gradient to growth rate ratios (G/R) were used in an effort to prevent constitutional supercooling and the subsequent formation of L(sub 2) droplets in advance of the solidification front during the growth of fibrous composite structures. Results demonstrated that hypermonotectic composites could be produced in samples up to two weight percent off of the monotectic composition by using a G/R ratio greater than or equal to 4.6 x 10(exp 4) C(s)/mm(sup 2) to avoid constitutional supercooling. For hypermonotectic samples processed with G/R ratios below 4.6 x 10(exp 4) C(s)/mm(sup 2), constitutional supercooling occurred and resulted in slight interfacial instability. For these samples, two methods of incorporation of the hypermonotectic liquid were observed and are reported. The correlation between the phase spacing, lambda, and the growth rate, R, was examined and was found to obey a relationship generally associated with a diffusion controlled coupled growth process. For samples with compositions ranging from the monotectic composition up to 2 percent off of the monotectic composition, data indicated that the square of the phase spacing (lambda) varied linearly with the inverse of the growth rate (R). DETERMINATION OF THE SURFACE CLEANLINESS OF METALS BY FT-IR SPECTROSCOPY
G. L. Powell and H. M. Meyer, III 16 Feb. 1993 4 p Presented at the DOE Compatibility, Aging and Service Life Conference, Aiken, SC, 20-22 Apr. 1993

(Contract DE-AC05-84OS-21400)
(DE93-013252; Y/DZ-990; CONF-9304103-6) Avail: CASI HC A01/MF A01

Remote-sensing 75 deg. specular (grazing angle with both s- and p-polarized light) reflectance mid-infrared spectroscopy has been used to inspect metal surfaces for contamination (i.e., cleanliness). This technique can analyze flat or convex surfaces with no restriction on the size of the specimen. Grazing angle specular reflectance off relatively flat metal objects is the most sensitive method of surface analysis with p-polarized light being absorbed by surface species and s-polarized light not absorbed by surface species. DOE

IONIC CONDUCTIVITY OF ALKALI HALIDES AND THEIR MIXTURES NEAR LIQUID-SOLID PHASE TRANSITION M.S. Thesis
Eli Shasha 2 Jun. 1992 46 p
(ITN-93-85222) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

The starting point was the assumption that the distribution of the different ions among the lattice sites is random if two salts are soluble in the solid state. This randomness imposes disorder into the structure, possibly leading to a glassy state. Ionic conductivity measurements were carried out in mixed and pure salts, in order to detect possible signs of vitrification. An alternating current (AC) bridge was used to measure the modulus of impdedance and the angle between the real and imaginary components of conductivity. Measurements of conductivity were taken at different frequencies, so that we were able to observe different phases by measuring the conductivity modulus and frequency dispersion. It is shown that these characteristics behave differently in each phase. The motivation for measuring conductivity (the reciprocal of resistivity) comes from the obvious relation of this property to a coefficient of diffusion or a reciprocal viscosity. Both are known to change dramatically (by several orders of magnitude) at the freezing points of alkali halide salts. Thus the phase state could be detected by measurements of conductivity. The highest conductivity is expected in the liquid state, where it is governed by movement of free ions. A glass transition is an alternative to a crystallization. Thus, the conductivity was measured over a temperature interval containing both the liquid and solid states. We also performed a temperature cycling in order to observe the dynamics of the system. Gland (Michigan Univ., Ann Arbor.), and Arnie R. Moodenbaugh (Brookhaven National Lab., Upton, NY.) 1993 6 p Presented at the Spring Meeting of the MRS, San Francisco, CA, 12-16 Apr. 1993
(Contract DE-AC02-76CH-00016)
(DE93-014325; BNL-48887; CONF-930405-12) Avail: CASI HC A02/MF A01

Direct comparisons between surface and bulk of diverse materials can be made by simultaneous electron yield (5 nm depth sensitivity) and fluorescence yield (200 nm) ultra soft x-ray absorption spectroscopy measurements utilizing a rapid sample interchange apparatus. For example the orientations of functional groups have been characterized at and near the surface of a series of model polymeric materials highlighting the chemical and molecular sensitivity of ultra-soft x-ray absorption spectroscopy. In addition we discuss a bulk sensitive use of fluorescence yield to non-destructively study a buried metal polymer interface. A second bulk sensitive example is the use of fluorescence yield oxygen K near edge x-ray spectroscopy as a method to determine the hole state density of high Tc materials. DOE

UPGRADING OF RAW NATURAL GAS USING HIGH-PERFORMANCE POLYMER MEMBRANES
S. A. Stern, H. S. Meyer (Gas Research Inst., Chicago, IL.), V. K. Venkataraman (Department of Energy, Morgantown, WV.), and H. D. Shoemaker (Department of Energy, Morgantown, WV.) 1993 7 p Presented at the AFS Seminar and Expo Annual Meeting, Chicago, IL, 3-6 May 1993 Sponsored by Gas Research Inst., Chicago, IL, and DOE, Morgantowm, WV
(DE93-014041; DOE/METC-C/93/7068; CONF-9305166-2) Avail: CASI HC A02/MF A01

The separation of CO2 and H2S from raw natural gas is essential for enhancing the heating value of the gas and for providing environmental safety during nation and use. Membrane separation processes are particularly useful for this application because they are inherently energy-efficient. Membrane processes also offer other important advantages, such as ease of scale-up due to module design, good space and weight efficiency and great flexibility in handling variations in the flow rate, pressure and composition of the raw natural gas streams. In a coordinated effort, the Gas Research Institute and the Department of Energy, Morgantown Energy Technology Center are funding an extensive study at Syracuse University on the relationships between the chemical structure of various polymers and their permeability to different gases. Based on criteria derived from this study, novel fluorine-containing polyimides that exhibit very high CO2/CH4, selectivities as well as significant H2S/CH4, selectivities were synthesized. These 'dense' (homogeneous) membranes separated various mixtures of CO2/CH4, and H2S/CH4/CO2 at 35 C (95 F) and at pressures up to 10 atm (147 psi). The results of these measurements agree well with computer simulations. The CO2 content of CH4/CO2 mixtures containing as much as 40 mole percent CO2 can be reduced with the polyamide membranes to pipeline specifications (less than or equal to 2 mole percent CO2. To reduce the H2S content of H2S/CH4/CO2 mixtures to pipeline specifications (less than or equal to 4 ppM H2S), the membranes are best combined with conventional gas-absorption processes, such as a selective amine. Such 'hybrid' processes for the upgrading of natural gas can be more economical than conventional gas-absorption processes alone. DOE

PROCUREMENT AND EXECUTION OF PCB ANALYSES: CUSTOMER-ANALYST INTERACTIONS
M. D. Erickson 1993 14 p Presented at the 5th International Conference for the Remediation of PCB Contamination, Houston, TX, 15-16 Mar. 1993
(Contract W-31-109-eng-38)
(DE93-009964; ANL/ER/CP-77861; CONF-9303123-1) Avail: CASI HC A03/MF A01

The practical application of PCB (polychlorinated biphenyl) analyses begins with a request for the analysis and concludes with provision of the requested analysis. The key to successful execution of this iteration is timely, professional communication between the requester and the analyst. Often PCB analyses are not satisfactorily executed, either because the requester failed to give adequate instructions or because the analyst simply 'did what he/she was told.' The request for and conduct of a PCB analysis represents a contract for the procurement of a product (information about the sample); if both parties recognize and abide by this contractual relationship, the process generally proceeds smoothly. Requesters may be corporate purchasing agents working from a scope of work, a sample management office, a field team leader, a project manager, a physician's office, or the analyst himself. The analyst with whom the requester communicates may be a laboratory supervisor, a sample-receiving department, a salesperson for the laboratory, or the analyst himself. The analyst conducting the analysis is often a team, with custody of the sample being passed from sample receiving to the extraction laboratory, to the cleanup laboratory, to the gas chromatography (GC) laboratory, to the data reduction person, to the package preparation person, to the quality control (QC) department for verification, and finally, to shipping. Where a team of analysts is involved, the requester needs a central point of contact to minimize confusion and frustration. For the requester-analyst interface to work smoothly, it must function as if it is a one-to-one interaction. This article addresses the pitfalls of the requester-analyst interaction and provides suggestions for improving the quality of the analytical product through the requester-analyst interface. DOE

COMPARATIVE IGNITION OF HEXANE AND OCTANE ISOMERS IN A SHOCK TUBE
A. Burcat (Technion - Israel Inst. of Tech., Haifa.), W. J. Pitz, and C. K. Westbrook Feb. 1993 23 p Presented at the 18th International

Conference on Shock Waves and Shock Tubes, Sendai, Japan, 21-26 Jul. 1992
(Contract W-7405-eng-48)
(DE93-016535; UCRL-JC-112692; CONF-9207205-1) Avail: CASI HC A03/MF A01

Ignition delay times of hexane isomers are investigated behind shock waves. Initial concentrations of fuel oxygen and argon and the post shock temperature were varied systematically in order to establish the influence of these parameters on the ignition delay time. The fuels used were n-octane, 2-methylpentane, and 3-methylpentane. The temperature range of the experiments was 1100-1700 K and the initial pressures were 55-200 torr. These experiments are compared with a similar set of experiments performed on octane isomers (n-octane; 2,2,4-trimethylpentane and 2,3,4-trimethylpentane), and the reaction mechanism developed for them. THERMOSOLUTAL CONVECTION AND MACROSEGREGATION IN DENDRITIC ALLOYS Final Technical Report
David R. Poirier and J. C. Heinrich Sep. 1993 52 p
(Grant NAG3-1060)
(NASA-CR-194039; NAS 1.26:194039) Avail: CASI HC A04/MF A01

A mathematical model of solidification, that simulates the formation of channel segregates or freckles, is presented. The model simulates the entire solidification process, starting with the initial melt to the solidified cast, and the resulting segregation is predicted. Emphasis is given to the initial transient, when the dendritic zone begins to develop and the conditions for the possible nucleation of channels are established. The mechanisms that lead to the creation and eventual growth or termination of channels are explained in detail and illustrated by several numerical examples. A finite element model is used for the simulations. It uses a single system of equations to deal with the all-liquid region, the dendritic region, and the all-solid region. The dendritic region is treated as an anisotropic porous medium. The algorithm uses the bilinear isoparametric element, with a penalty function approximation and a Petrov-Galerkin formulation. The major task was to develop the solidification model. In addition, other tasks that were performed in conjunction with the modeling of dendritic solidification are briefly described. ANCHORING STRATEGIES FOR BIMETALLIC SPECIES IN ZEOLITES
T. Bein Mar. 1993 7 p
(Contract DE-FG02-92ER-14281)
(DE93-015622; DOE/ER-14281/1) Avail: CASI HC A02/MF A01

We explore a new approach by introducing heterobinuclear organometallic compounds for linking catalytic functions to zeolite frameworks. With two different metals present, the complexes are being anchored to the support via one oxophilic metal, ligand exchange and catalytic reactions may proceed at the second metal center. Anchoring chemistry, thermal stability and reactivity of Me3SnMn(CO)5 in zeolite NaY and acid forms of zeolite Y was studied with X-ray absorption spectroscopy (Sn, Mn edge EXAFS) and in-situ FTIR/TPD-MS techniques. Subsequently, the tin-cobalt complex Me3SnCo(CO)4 has been a focus of detailed synthetic and spectroscopic studies. The reactivity of tricarbonyl (cyclopentadienyl) (trimethylstannyl) molybdenum in new mesoporous hosts has been explored. A recent development is the design of vanadium oxo species in different micro- and mesoporous hosts. These are of great interest for the selective reduction of nitrogen oxides by ammonia, and selective oxidation of different hydrocarbons, such as xylenes, olefines and alkanes. Combination analytical techniques used to probe local structural changes at the molecular level, include EXAFS (Extended X-Ray Absorption Fine Structure) spectroscopy utilizing synchrotron radiation, in situ FT-IR coupled to thermodesorption/MS, UV-NIR, and CCD Raman. EFFECT OF PRESSURE ON ORDER AND STABILITY IN ALLOYS: THE CASE OF Al-Ge
P. E. A. Turchi, M. Sluiter, and G. M. Stocks (Oak Ridge National Lab., TN.) 1 Dec. 1992 8 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992

(Contracts W-7405-eng-48; DE-AC05-84OR-21400)
(DE93-013842; UCRL-JC-110687; CONF-921101-115) Avail: CASI HC A02/MF A01

A parameter-free approach to phase stability in substitutional alloys is applied to the influence of pressure on order-disorder phenomena in Al-Ge. The methodology is based upon an application of the Generalized Perturbation Method to the Korringa-Kohn-Rostoker scattering formulation of the Coherent Potential Approximation. For fcc-based Al-Ge alloys, it is shown that the tendency towards phase separation at normal pressure originates from a structural difference between the pure species. By applying pressure, the structural energy difference is reduced, and a significant increase in the tendency towards order, especially for Al-rich alloys, is theoretically observed, leading, as an example, to the possible observation of a DO(sub 22) ordered state around 25 at. %. The electronic origin of the ordering tendencies induced by pressure is discussed and the theoretical predictions are related to experimental facts. DOE

MULTIPHASE EQUATION OF STATE FOR IRON
G. I. Kerley Feb. 1993 64 p
(Contract DE-AC04-76DP-00789)
(DE93-013956; SAND-93-0027) Avail: CASI HC A04/MF A01

The PANDA code is used to build a multiphase equation of state (EOS) table for iron. Separate EOS tables were first constructed for each of the individual phases. The phase diagram and multiphase EOS were then determined from the Helmholtz free energies. The model includes four solid phases (alpha, gamma, delta, and epsilon) and a fluid phase (including the liquid, vapor, and supercritical regions). The model gives good agreement with experimental thermophysical data, static compression data, phase boundaries, and shock-wave measurements. Contributions from thermal electronic excitation, computed from a quantum-statistical-mechanical model, were found to be very important. This EOS covers a wide range of densities (0-1000 g/cm(sup 3)) and temperatures (0-1.2 x 10(sup 7) K). It is also applicable to RHA steel. The new EOS is used in hydrocode simulations of plate impact experiments, a nylon ball impact on steel, and the shaped charge perforation of an RHA plate. The new EOS table can be accessed through the SNL-SESAME library as material number 2150. DOE

ROLE OF MICROSTRUCTURE ON FATIGUE DURABILITY OF ALUMINUM AIRCRAFT ALLOYS
J. R. Brockenbrough, R. J. Bucci, A. J. Hinkle, J. Liu, and P. E. Magnusen 15 Apr. 1993 131 p
(Contract F33615-92-C-5915)
(AD-A265627) Avail: CASI HC A07/MF A02

The goal of this program is to affect change in metallic aircraft life assessment methodology through quantitative understanding of how material microstructure impacts fatigue durability performance. Various studies have shown that most metal cracking problems encountered in service involve fatigue. Further studies have shown that metallurgical discontinuities and/or manufacturing imperfections often tend to exacerbate such problems by causing cracks to occur sooner than expected. This program concentrates on the initiation and early growth stage of fatigue cracks where the majority of structural life is spent. The program has two general objectives: (1) quantifying the effect of aluminum alloy microstructure on early stage fatigue damage evolution and growth, and (2) establishing an analytical framework to quantify structural component life benefits attainable through modification of intrinsic material microstructure. The modeling approach taken couples quantitative characterizations of representative material microstructures with concepts of probabilistic fracture mechanics. DTIC

HIGH-TEMPERATURE CORROSION AND PROTECTION OF MATERIALS
P. F. Tortorelli 19 Jun. 1992 13 p
(Contract DE-AC05-84OR-21400)
(DE93-011072; ORNL/FTR-4283) Avail: CASI HC A03/MF A01 (US Sales Only)

Two papers were presented by P.F. Tortorelli at the Third International Symposium on High-Temperature Corrosion and Protection of Materials in Les Embiez, France. Substantial interest was shown in current ORNL research on iron aluminides, Cr-Nb alloys, and mechanical properties of oxide scales. At least two other organizations are actively pursuing applications for iron aluminides. A good mix of basic and applied research papers contributed to the value of the symposium. Dr. Tortorelli also visited Harwell Laboratory and Cranfield Institute of Technology in the United Kingdom (UK). At Harwell, he discussed experimental procedures for very-high-temperature oxidation and innovative methods of corrosion analysis. During his visit to Cranfield, he was briefed on the modeling of erosion and corrosion processes and had discussions related to the mechanical properties of oxide scales. Efforts in corrosion, erosion, and coatings at Cranfield are extensive and impressive. DOE

GAS ATOMIZED Er3Ni POWDER FOR CRYOCOOLER APPLICATIONS
I. E. Anderson, M. G. Osborne, H. Takeya, and K. A. Gschneidner, Jr. 1992 14 p Presented at the 7th International Cryocooler Conference, Santa Fe, NM, 15-19 Nov. 1992
(Contract W-7405-eng-82)
(DE93-011564; IS-M-746; CONF-921130-2) Avail: CASI HC A03/MF A01

A high pressure gas atomization (HPGA) approach was developed to produce uniform spherical powders of high purity Er3Ni and 3 batches of about 1.3 kg each were prepared. Average yield of high quality spherical powders between 0.15 and 0.35mm was about 16% of the initial atomizer charge weight. Microstructural analysis of sectioned powder samples revealed single phase particles with some internal cracking but no evidence of an oxidized surface shell. Chemical analysis and x-ray diffraction measurements verified that single phase particles of the stoichiometric composition had been generated. Vacuum fusion measurements indicated that the powder contained 2600 ppM oxygen. The heat capacity of a hot pressed, partially sintered Er3Ni powder sample was measured from 2 to 80K; results indicated a maximum heat capacity of 0.43 J/cu cm K at 7K and the peak appears to be about 0.04 J/cu cm K higher and narrower than reported by Sahashi. The Sahashi heat capacity peak has two maxima, suggesting the two phases in their material. Our Er3Ni powder has a larger heat capacity than Pb over the entire range of temperatures up to about 25K which should permit a lower final temperature for a cryocooler stage composed of this material. DOE

INTERFACIAL PRECIPITATION, SEGREGATION AND DEFORMATION IN ALLOY 600: IMPLICATIONS ON PRIMARY-SIDE IGSCC
S. M. Bruemmer Apr. 1993 7 p Presented at the Alloy 600 Experts Meeting, Warrenton, VA, 5-9 Apr. 1993
(Contract DE-AC06-76RL-01830)
(DE93-013161; PNL-SA-22257; CONF-9304146-1) Avail: CASI HC A02/MF A01

A great many unknowns still exist concerning the mechanisms controlling intergranular stress corrosion cracking (IGSCC) of alloy 600 in high-temperature, deaerated water environments. Any proposed mechanism must involve the microstructure, microchemistry and mechanical properties of grain boundary regions. To facilitate basic understanding, specific aspects of alloy 600 metallurgy are reviewed and discussed. Interfacial carbide precipitation, chromium depletion, impurity segregation and local deformation characteristics are examined and related to IGSCC behavior. Purpose of this paper is to provide information, and prompt discussion, on these various issues for the EPRI Alloy 600 Experts Meeting. DOE

EFFECT OF MICROSTRUCTURE ON PASSIVE FILM FORMATION AND BREAKDOWN ON Al ALLOYS Final Report, 15 Dec. 1988 - 14 Dec. 1992
J. Kruger, J. W. Wagner, R. S. Lillard, and C. C. Streinz 31 May 1993 28 p
(Contract N00014-89-J-1180)
(AD-A265339) Avail: CASI HC A03/MF A01

Two in situ techniques, dynamic imaging microellipsometry (DIM) and local impedance spectroscopy (LEIS), were developed and applied to a study of the effect of microstructure on passive film formation and breakdown on Al-Ta alloys. DIM acquires ellipsometric data (thickness and optical constants of the films on surfaces) at a spatial resolution of ca. 20 micrometers using a radiometric full-field imaging approach. LEIS is an electrochemical impedance technique that generates local a.c. impedance data by measuring a.c. solution current densities very near the microstructural features of an electrode surface. The DIM technique was used to look at passive film formation in the Al3Ta precipitate, the dealloyed zone adjacent to the precipitate, and the solid solution phase that is present in Al-Ta alloys. The DIM technique observed different film thicknesses and optical constants for the films that form on these phases at potentials in the passive regions. The LEIS technique was used to study the precipitate and the region surrounding it under conditions where passive film breakdown occurs. Using these techniques, insight was obtained into the passive film formation and breakdown processes that control localized corrosion. DTIC

INCOMPLETE MELTING OF THE Au(100) SURFACE
G. Bilalbegovic and E. Tosatti Jan. 1993 36 p
(DE93-623192; IC-93/7) Avail: CASI HC A03/MF A01 (US Sales Only)

We study the high-temperature disordering of the reconstructed Au(100) surface by molecular dynamics simulation using a many-body interatomic potential. We find that the surface deconstructs at 0.8T(sub m) in good agreement with experimental data, but proper surface melting does not occur close to the bulk melting point. Instead there is an in-plane disordering of the two topmost layers. The thickness of the disordered region remains constant with increasing temperature, indicating blocked, or incomplete, melting of the (100) crystalline substrate. An analysis of the structure reveals that crystalline and disordered islands coexist on two first surface layers for temperature between deconstruction and bulk melting. DOE

THE CORROSION BEHAVIOR OF 8001 Al UNDER HEAT-TRANSFER CONDITIONS IN AN AQUEOUS LOOP SYSTEM
R. E. Pawel, D. K. Felde, M. T. McFee, and J. A. Clinard Apr. 1993 135 p
(Contract DE-AC05-84OR-21400)
(DE93-013450; ORNL/NPR-92/65) Avail: CASI HC A07/MF A02 (US Sales Only)

Specimens of 8001 aluminum were exposed to flowing water under heat-transfer conditions relevant to the proposed New Production Reactor-heavy-water reactor (NPR-HWR) in a Corrosion Test Loop System. The growth of oxide films on the reacting surfaces was characterized by temperature measurements on the specimen during the course of the experiments and by post-test examinations and analyses of the specimens. For all tests, the major reaction product was boehmite (Al2O3(center dot)H2O) with, in many instances, a thin, iron-rich outer layer that formed as a consequence of aqueous mass transport from the cooler stainless steel sections of the loop. In a series of five tests, each up to eight weeks in duration, the measured film growth rates were shown to be sensitive to both thermal-hydraulic and chemical variables and were compared to the predictions of existing data correlations. PREPARATION AND CHARACTERIZATION OF RAPIDLY SOLIDIFIED Al-Li ALLOYS Ph.D. Thesis [ELABORATION ET CARACTERISATION D'ALLIAGES AL-LI SOLIDIFIES RAPIDEMENT]
Mohamed Hajjaji Jun. 1990 296 p In FRENCH
(ISBN-0-315-58948-5; CTN-93-60855) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

A study was conducted to study the effects of rapid solidification processing by free-jet chill-block melt spinning (FJCBMS) on the microstructure and precipitation characteristics of Al-Li ribbons containing up to 10 weight percent Li for various wheel speeds and preparation atmospheres. Ribbons were prepared in a specially constructed melt spin apparatus to control the major extrinsic parameters that affect ribbon morphology, topography, and microstructure as well as to provide an inert atmosphere for alloying. The preparation atmosphere has a marked effect on the volatilization of Li during processing, the wetting of the liquid Al-Li alloy on the chill block, and the formation of the Li2O and Li2CO3 contaminants. A relationship was found between the ribbon thickness and the wheel velocity which is independent of Li concentration and solidification mechanism. Changes in Li content also have a marked effect on the solidification mechanisms. For ribbons containing up to 1.79 percent Li, solidification occurs under the melt puddle and the ribbon microstructure consists mainly of columnar grains without Al3Li precipitation. Ribbons with over 3 percent Li solidify away from the effects of the puddle and their

microstructure exhibits featureless and segregated zones. Two distinct mechanisms of Al3Li precipitation occur for the 1.79 percent Li ribbon at aging temperatures of 66, 75, and 200 C. Author (CISTI)

First-principles calculations were performed for the hydrogen-yttrium system using the pseudopotential method within the local density functional approximation (LDA). We have studied the nature of hydrogen pairing in the solid solution phase ((alpha)-YH(x)) and identified the connection with electronic structure. The vibrational spectra, diffusion barrier, and migration path were also investigated. We have also studied the binding characteristics for different interstitial sites and the (420)-plane ordering of octahedral hydrogen in (beta)YH(2+x) within the lattice gas model. Temperature-composition phase diagram was calculated by cluster variational method with the multibody interactions extracted from total energies of related ordered structures. Moreover, the discovery of Peierls distortions in YH3 explained the unusual hydrogen displacements found in neutron diffraction and the possibility of an excitonic insulating ground state was speculated. Several new improvements in the calculational techniques have also been developed: separable nonlocal pseudopotentials, a scheme to calculate the full phonon spectrum, and distance dependent tight-binding parameters. The Ru(0001)-H system was also studied. DOE

TENSILE PROPERTIES OF LE-7 ENGINE MATERIAL WITH WELDED JOINT Report No. 1 [LE-7 YOU ZAIRYOU YOUSETSU TSUGITE NO HIPPARI TOKUSEI]
Tomoyuki Hashimoto, Yoshiaki Watanabe, and Mitsumasa Sakamoto Dec. 1992 15 p In JAPANESE
(NAL-TR-1188; JTN-93-80508) Avail: CASI HC A03/MF A01

The LE-7 engine which will be used as the first stage main engine for the H-2 rocket has been under development in Japan. This engine has many welded joints that have developed a variety of problems. Therefore, tensile properties and microstructures of Inconel-718 test specimens with welded joints were investigated at various temperatures in high pressure hydrogen and helium environments to study the fundamental characteristics of the welded joints. The results indicated that the ductility of the welded joints was less than that of the parent metal and that the deterioration of ductility was due to the dendrite structure of the Ni3Nb phase.

MODERN ALUMINIUM SHEET ALLOYS FOR AEROSPACE APPLICATIONS
R. J. H. Wanhill, L. Schra, and W. G. T. tHart 20 Feb. 1992 11 p Presented at the Third International Conference on Aluminum Alloys, Trondheim, Norway, 22-27 Jun. 1992 Sponsored by Netherlands Agency for Aerospace Programs, Delft, and EEC
(NLR-TP-92057-U; ETN-93-94344) Avail: CASI HC A03/MF A01

Several aluminum sheet alloys which have emerged as candidates for replacing the industry standard damage tolerant AlCuMg alloy 2024-T3 in aircraft structures are considered. These alloys include the AlLiCuMgZr (Al-Li) alloys 2091-T84 and 8090-T81, and the AlMgSiCu alloy 6013-T6. These alloys are compared with respect to mechanical properties, fracture toughness and crack resistance, fatigue crack growth under constant amplitude and flight simulation loading, and corrosion and stress corrosion resistances. The practical significance of the results is discussed, and the current status and prospects are indicated. ESA

EXCIMER LASER SURFACE PROCESSING OF TITANIUM
T. R. Jervis, K. M. Hubbard, T. G. Zocco, L. Foster, M. Nastasi, and J. R. Tesmer 1993 26 p Presented at the Annual Meeting of the Minerals, Metals and Materials Society, Denver, CO, 22 Feb. 1993
(Contract W-7405-eng-36)
(DE93-012633; LA-UR-93-1142; CONF-9302103-2) Avail: CASI HC A03/MF A01

We have examined the effect of laser surface processing of Ti alloys using pulsed excimer laser light at 248 nm. Thermal transformations of the surface are accomplished by the heating of the surface and rapid cooling. Alloying and formation of compounds can be obtained by melting and mixing surface layers into the material and by gas alloying. Multiple melting-resolidification cycles result in the inter-diffusion of surface layers in the liquid state and the diffusion of gas species into the material. The effect of alloying from both solid and gas sources and the effects of thermal transformations on the microstructure and surface hardness properties of these alloys will be examined. DOE

THE ASCOR TEST: A SIMPLE AUTOMATED METHOD FOR STRESS CORROSION TESTING OF ALUMINIUM ALLOYS
L. Schra and F. F. Groep (National Aerospace Lab., Emmeloord, Netherlands.) 7 Nov. 1991 22 p Submitted for publication
(NLR-TP-91438-U; ETN-93-94341) Avail: CASI HC A03/MF A01

A simple automated stress corrosion testing method called the ASCOR (Automated Stress COrrosion Ring) test was developed to test aluminum alloys according to the ASTM specification G44. The method involves testing cylindrical or sheet specimens in a loading ring provided with strain gauges to measure the load. Initiation of a stress corrosion crack results in a small load decrease. During the test, the load is measured periodically and stored in a data acquisition system controlled by a personal computer. A specific load decrease is used as the criterion for stress corrosion crack initiation. The main advantages of the method are that a large number of specimens can be tested simultaneously in a climate chamber, and that stress corrosion cracking initiation lives can be determined according to a clearly defined criterion without time consuming and subjective inspections, and without disturbing the test procedure. The results of comparisons of the application of tensile test methods for metals to SiC particulate reinforced aluminum alloy Metal Matrix Composites (MMC) are presented. For the first phase a material blended from powders was extruded and machined into rectangular specimens for test by about thirty organizations. For the second phase a commercial material was used and machined into both rectangular and round specimens for test by essentially the same organizations as in the first phase. The major factors which contribute to uncertainties in the measurement of tensile properties of MMC are identified. Recommendations for the further work required in order for an agreed tensile test method for particulate reinforced MMC to be developed are made. ESA

FATIGUE CRACK INITIATION AND PROPAGATION IN ALUMINUM ALLOYS 8090 AND 2124 IN HYDROGENOUS ATMOSPHERES Ph.D. Thesis
Orval H. Hilliard 1992 235 p
Avail: Univ. Microfilms Order No. DA9312470

An Al-Li-Cu-Mg-Zr alloy, 8090-T8 (short transverse orientation), was evaluated with corrosion fatigue tests. This material was compared with 2124-T851 in dry helium and hydrogen-bearing atmospheres of dry hydrogen and water vapor saturated helium. The microstructures of both alloys were characterized using microscopy with image analysis. The monotonic mechanical properties were determined by tensile testing. Both 8090-T8 and 2124-T851, in short transverse orientation, suffered loss of ductility from the presence of large precipitate particles. This was more severe for 8090-T8. Fatigue crack initiation specimens were evaluated using replicas and SEM examination. Atmosphere and stress amplitude were variables. The environments were dry helium, dry hydrogen, and saturated helium at ambient temperatures. The response of the alloys to these environments was evaluated by qualitative observation of slip bands, surface crack count, and number of cycles to failure. Low cycle corrosion fatigue tests provided data for evaluating strain hardening characteristics and determining the fatigue strength, ductility, and cyclic strength constants. Fatigue performance in inert and hydrogen-bearing environments was compared over a range of strain amplitudes. The variation of fatigue ductility coefficients and exponents with environment aggressiveness clearly shows effects by environment on strain controlled fatigue behavior, e.g. the fatigue ductility exponents changed by 50 percent or more between dry and saturated helium. Load controlled fatigue under fully reversed loading, in dry helium, hydrogen, or saturated helium, provided S/N plots to illustrate the effects of aggressive environments. The presence of water vapor decreased the fatigue life of 8090-T8 by an order of magnitude at low stress amplitudes. The fatigue life of 2124-T851 decreased in dry hydrogen, but was unaffected in saturated helium. At high stress amplitudes, 2124-T851 is superior to 8090-T8 in all tested environments. At low stress amplitudes, 8090-T8 is superior in dry environments. In saturated helium, 2124-T851 is superior at all stress amplitudes. A model was proposed to rationalize the observed effects of the aggressive hydrogenous atmosphere. This model suggests that particle matrix decohesion is enhanced in the aggressive environments. If this is true, then particle-matrix decohesion would occur at smaller particles than in inert atmospheres. Decohesion would continue to occur at large particles. Dissert. Abstr.

ROLE OF MICROSTRUCTURE ON FATIGUE DURABILITY OF ALUMINUM AIRCRAFT ALLOYS Interim Status Report
9 Mar. 1993 26 p
(Contract N00014-91-C-0128)
(AD-A266350) Avail: CASI HC A03/MF A01

Alcoa historical 7050 fatigue test data has been assembled and reviewed. The range of microstructures examined in the program has been expanded from two in the contract proposal to five. In addition to the old and new quality thick plate, the program includes low porosity thick plate, low particle thick plate, and thin plate. These materials provide a range of microstructures/fatigue failure modes to help understand and model early stage fatigue damage. Though the scope of the program has expanded, the total program cost to the Navy has not changed. The fatigue test data on additional microstructural variants of 7050 have been assembled. Fractography of failed coupon specimens has been completed. The microstructural features controlling fatigue initiation have been identified. Samples of old and new quality plate have been supplied to the UCLA team in support of their ONR program. DTIC

MICROSTRUCTURAL EVOLUTION OF NARloy-Z AT ELEVATED TEMPERATURES
J. Singh, G. Jerman, B. N. Bhat, and R. Poorman Sep. 1993 29 p
(NASA-TM-108419; NAS 1.15:108419) Avail: CASI HC A03/MF A01

Microstructural evolution was studied in samples of wrought and vacuum plasma sprayed (VPS) NARloy-Z exposed to temperatures up to 970 C (1,780 F) for up to 60 h. Samples were heated in a vacuum furnace, followed by rapid quenching in helium (He) gas at a cooling rate of 166 C (300 F) per second. Microstructural analyses were conducted using optical microscopy, scanning electron microscopy (SEM), and electron probe microanalysis (EPMA). In both the wrought and VPS conditions, precipitates rich in silver (Ag) and zirconium (Zr) were present in the matrix and at the grain boundaries even after long exposure to elevated temperatures. Islands rich in oxygen (O2) and Zr were also observed, as well as incipient melting at the grain boundary triple points. Results indicated that the alloy cannot be homogenized by heat treatment at elevated temperatures. Author (revised)

THE MICROSTRUCTURAL RESPONSE OF NEAR GAMMA-TiAl+W TO HEAT TREATMENT
J. Beddoes, L. Zhao (Institute for Aerospace Research, Ottawa, Ontario.), and W. Wallace (Institute for Aerospace Research, Ottawa, Ontario.) 1992 5 p Sponsored by Dept. of National Defence
(DSIS-93-00237; CTN-93-60799) Avail: CASI HC A01

The phase transformations and kinetics of the grain coarsening reaction occurring during heat treatment in the alpha+gamma and alpha phase fields were investigated for powder metallurgically (PM) produced near gamma-TiAl+W alloy. This alloy was chosen because the W addition promotes the formation of third phase W-rich beta. As well, a fine initial microstructure exists due to the inherent rapid solidification of PM processing. Potentially, these factors can alter the transformation and grain growth kinetics. Two series of heat treatments were undertaken: two hours at temperatures ranging from 1250 C to 1400 C, and treatment at 1400 C for times ranging from 10 to 240 minutes. Heat treatment in the single phase region was found to cause rapid transformation of gamma to alpha in under 10 minutes. The grain growth kinetics at 1400 C for TiAl+W are slower than for other near gamma-TiAl alloys. The dependence of grain size D on heat treatment time t can be described by the equation D=70.3t raised to the 0.29 power. Heat treatment for over three hours at 1400 C produces a grain size of about 300 microns. During heat treatment in the alpha+gamma region, alpha plates develop on the (111) planes. Author (CISTI)

THE INFLUENCE OF A MICROGRAVITY ENVIRONMENT ON THE DENDRITIC MORPHOLOGY DURING DIRECTIONAL SOLIDIFICATION OF HYPOEUTECTIC Al-Si ALLOYS Final Technical Report, 1 May 1991 - 30 Apr. 1992
Richard N. Grugel 1993 7 p
(Grant NAGw-2540)
(NASA-CR-194139; NAS 1.26:194139) Avail: CASI HC A02/MF A01

NASA grant NAGW-2540 provided the opportunity to evaluate and extend ongoing studies of directionally solidified Al-Si alloys. Microstructural development was further characterized in terms of solidification processing parameters; novel relationships between processing and development of dendrite trunk diameters and tertiary dendrite arm spacings were found. This has resulted in three publications (one in print, one in press, and one in review). Microstructural development under conditions of controlled acceleration during directional solidification has been investigated; this has culminated in a Master's degree and will be submitted for publication. The above work not only contributes to our understanding of solidification phenomena but also defines the processing parameters for a successful microgravity experiment while providing a data base to which mu g samples can be unequivocally compared and evaluated. RADIATION HARDENING AND RADIATION-INDUCED CHROMIUM DEPLETION EFFECTS ON INTERGRANULAR STRESS CORROSION CRACKING OF AUSTENITIC STAINLESS STEELS
S. M. Bruemmer and E. P. Simonen Mar. 1993 14 p Presented at the NACE Annual Corrosion Conference and Materials Performance and Corrosion Show, New Orleans, LA, 7-12 Mar. 1993
(Contract DE-AC06-76RL-01830)
(DE93-011602; PNL-SA-21491; CONF-930318-9) Avail: CASI HC A03/MF A01

Available data on neutron-irradiated materials have been analyzed, and correlations were developed between fluence, yield strength, grain boundary chromium concentration, and cracking susceptibility in high-temperature water environments. Large heat-to-heat differences in critical fluence (0.2 to 2.5 n/sq cm) for IGSCC are documented. In many cases, this variability is consistent with yield strength differences among irradiated materials. IGSCC correlated better to yield strength than to fluence for most heats suggesting the possible role of radiation-induced hardening (and microstructure) in cracking. However, isolated heats reveal a wide range of yield strengths from 450 to 800 MPa necessary to promote IGSCC which cannot be understood by strength effects alone. Grain boundary Cr depletion explain differences in IGSCC susceptibility for irradiated stainless steels. Cr contents versus SCC shows that all materials showing IG cracking have some grain boundary depletion (greater than or equal to 2%). Grain boundary Cr concentrations for cracking (below approximately 16 wt %) are in good agreement with similar SCC tests on unirradiated 304 SS with controlled depletion profiles. Heats that prompt variability in the yield strength correlation are accounted for by differences in their interfacial Cr contents. Certain stainless steels are more resistant to cracking even though they have significant radiation-induced Cr depletion. It is proposed that Cr depletion is required for IASCC, but observed susceptibility is modified by other microchemical and microstructural components. DOE

CONTAINERLESS PROCESSING OF UNDERCOOLED MELTS Final Report, 1 Mar. 1989 - 28 Feb. 1993
J. H. Perepezko 1993 28 p
(Grant NAG8-771)
(NASA-CR-194350; NAS 1.26:194350) Avail: CASI HC A03/MF A01

The investigation focused on the control of microstructural evolution in Mn-Al, Fe-Ni, Ni-V, and Au-Pb-Sb alloys through the high undercooling levels provided by containerless processing, and provided fundamental new information on the control of nucleation. Solidification analysis was conducted by means of thermal analysis, x-ray diffraction, and metallographic characterization on samples processed in a laboratory scale drop tube system. The Mn-Al alloy system offers a useful model system with the capability of phase separation on an individual particle basis, thus permitting a more complete understanding of the operative kinetics and the key containerless processing variables. This system provided the opportunity of analyzing the nucleation rate as a function of processing conditions and allowed for the quantitative assessment of the relevant processing parameters. These factors are essential in the development of a containerless processing model which has a predictive capability. Similarly, Ni-V is a model system that was used to study duplex partitionless solidification, which is a structure possible only in high under cooling solidification processes. Nucleation kinetics for the competing bcc and fcc phases were studied to determine how this structure can develop and the conditions under which it may occur. The Fe-Ni alloy system was studied to identify microstructural transitions with controlled variations in sample size and composition during containerless solidification. This work was forwarded to develop a microstructure map which delineates regimes of structural evolution and provides a unified analysis of experimental observations. The Au-Pb-Sb system was investigated to characterize the thermodynamic properties of the undercooled liquid phase and to characterize the glass transition under a variety of processing conditions. By analyzing key containerless processing parameters in a ground based drop tube study, a carefully designed flight experiment may be planned to utilize the extended duration microgravity conditions of orbiting spacecraft. LIQUID METAL DROP EJECTION Final Report
B. T. Khuri-Yakub Aug. 1993 3 p
(Grant NAG3-1253)
(NASA-CR-193718; NAS 1.26:193718) Avail: CASI HC A01/MF A01

The aim of this project was to demonstrate the possibility of ejecting liquid metals using drop on demand printing technology. The plan was to make transducers for operation in the 100 MHz frequency range and to use these transducers to demonstrate the ability to eject drops of liquid metals such as gallium. Two transducers were made by indium bonding piezoelectric lithium niobate to quartz buffer rods. The lithium niobate plates were thinned by mechanical polishing to a thickness of 37 microns for operation at 100 MHz. Hemispherical lenses were polished in the opposite ends of the buffer rods. The lenses, which focus the sound waves in the liquid metal, had an F-number equals 1. A mechanical housing was made to hold the transducers and to allow precise control over the liquid level above the lens. We started by demonstrating the ability to eject drops of water on demand. The drops of water had a diameter of 15 microns which corresponds to the wavelength of the sound wave in the water. A videotape of this ejection was made. We then used a mixture of Gallium and Indium (used to lower the melting temperature of the Gallium) to demonstrate the ejection of liquid metal drops. This proved to be difficult because of the oxide skin which forms on the surface of the liquid. In some instances, we were able to eject metal drops, however, this was not consistent and reproducible. An experiment was set up at NASA-Lewis to stabilize the process of drop on demand liquid metal ejection. The object was to place the transducer and liquid metal in a vacuum station so that no oxide would form on the surface. We were successful in demonstrating that liquid metals could be ejected on demand and that this technology could be used for making sheet metal in space. Author (revised)

REVERSE MICELLE SYNTHESIS OF NANOSCALE METAL CONTAINING CATALYSTS
J. G. Darab, J. L. Fulton, and J. C. Linehan Mar. 1993 8 p Presented at the 205th American Chemical Society National Meeting, Denver, CO, 28 Mar. - 2 Apr. 1993
(Contract DE-AC06-76RL-01830)
(DE93-012869; PNL-SA-21663; CONF-930304-19) Avail: CASI HC A02/MF A01

The need for morphological control during the synthesis of catalyst precursor powders is generally accepted to be important. In the liquefaction of coal, for example, iron-bearing catalyst precursor particles containing individual crystallites with diameters in the 1-100 nanometer range are believed to achieve good dispersion throughout the coal-solvent slurry during liquefaction 2 runs and to undergo chemical transformations to catalytically active iron sulfide phases. The production of the nanoscale powders described here employs the confining spherical microdomains comprising the aqueous phase of a modified reverse micelle (MRM) microemulsion system as nanoscale reaction vessels in which polymerization, electrochemical reduction, and precipitation of solvated salts can occur. The goal is to take advantage of the confining nature of micelles to kinetically hinder transformation processes which readily occur in bulk aqueous solution in order to control the morphology and phase of the resulting powder. We have prepared a variety of metal, alloy, and metal- and mixed metal-oxide nanoscale powders from appropriate MRM systems. Examples of nanoscale powders produced include Co, Mo-Co, Ni3Fe, Ni, and various oxides and oxyhydroxides of iron. Here, we discuss the preparation and characterization of nickel metal (with a nickel oxide surface layer) and iron oxyhydroxide MRM nanoscale powders. We have used extended x-ray absorption fine structure (EXAFS) spectroscopy to study the chemical polymerization process in situ, x-ray diffraction (XRD), scanning and transmission electron microcroscopies (SEM and TEM), elemental

analysis, and structural modelling to characterize the nanoscale powders produced. The catalytic activity of these powders is currently being studied. DOE

BAKEOUT: A COMPUTER PROGRAM FOR PREDICTING DIFFUSIVE OUTGASSING FROM STAINLESS STEEL
M. P. Weis Dec. 1992 11 p Presented at the Pressure Vessels and Piping Conference, Denver, CO, 25-29 Jul. 1993
(Contract DE-AC06-87RL-10930)
(DE93-012613; WHC-SA-1361; CONF-930702-24) Avail: CASI HC A03/MF A01

The outgassing load from a leak-tight and well-baked vacuum vessel is frequently dominated by the diffusive outgassing of hydrogen gas from the materials of which the vessel is constructed. Stainless steel, in particular, can be a major source of hydrogen. The diffusive transport of gas through materials is governed by the second order partial differential equation, D (partial derivative)(sup 2)C/(partial derivative)X(sup 2) = (partial derivative)C/(partial derivative)t, known as Fick's Law. Two alternate solutions to this equation give exact numerical answers of the diffusive outgassing rate versus time. A simplified approximation of each solution allows prediction of both the short-term and the long-term behavior. BAKEOUT, a computer program based on Fick's Law, was developed to predict an elevated temperature step function of time (that is, a bakeout) that will achieve a desired hydrogen diffusive outgassing rate from a stainless steel vessel under vacuum. This paper presents the mathematical development of the computer program and an example case. DOE

MICROSTRUCTURAL INFLUENCES ON THE MECHANICAL PROPERTIES OF SOLDER
J. W. Morris, Jr., J. L. F. Goldstein, and Z. Mei Apr. 1993 48 p Presented at the 3rd International Workshop on Materials and Mechanics Issues of Solder Alloy Applications, Sante Fe, NM, 9-11 Sep. 1993
(Contract DE-AC03-76SF-00098)
(DE93-015044; LBL-34012; CONF-9209360-1) Avail: CASI HC A03/MF A01

Intent of this book is to review analytic methods for predicting behavior of solder joints, based on continuum mechanics. The solder is treated as a continuous, homogeneous body, or composite of such bodies, whose mechanical behavior is uniform and governed by simple constitutive equations. The microstructure of a solder joint influences its mechanical properties in three ways: it governs deformation and failure; common solders deform inhomogeneously; and common solders are microstructurally unstable. The variety of microstructures often found in solder joints are briefly reviewed, and some of the ways are discussed in which the microstructure influences the common types of high-temperature mechanical behavior. INVESTIGATIONS OF LOW-TEMPERATURE NEUTRON EMBRITTLEMENT OF FERRITIC STEELS
K. Farrell, S. T. Mahmood, R. E. Stoller, and L. K. Mansur 1992 28 p Presented at the 20th Water Reactor Safety Information Meeting, Bethesda, MD, 21-23 Oct. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015460; CONF-921007-32) Avail: CASI HC A03/MF A01

Investigations were made into reasons for accelerated embrittlement of surveillance specimens of ferritic steels irradiated at 50 C at the High Flux Isotope Reactor (HFIR) pressure vessel. Major suspects for the precocious embrittlement were a highly thermalized neutron spectrum, a low displacement rate, and the impurities boron and copper. None of these were found guilty. A dosimetry measurement shows that the spectrum at a major surveillance site is not thermalized. A new model of matrix hardening due to point defect clusters indicates little effect of displacement rate at low irradiation temperature. Boron levels are measured at 1 wt ppM or less, inadequate for embrittlement. Copper at 0.3 wt percent and nickel at 0.7 wt percent are shown to promote radiation strengthening in iron binary alloys irradiated at 50 to 60 C, but no dependence on copper and nickel was found in steels with 0.05 to 0.22 percent Cu and 0.07 to 3.3 percent Ni. It is argued that copper impurity is not responsible for the accelerated embrittlement of the HFIR surveillance specimens. The dosimetry experiment has revealed the possibility that the fast fluence for the surveillance specimens may be underestimated because the stainless steel monitors in the surveillance packages do not record an unexpected component of neutrons in the spectrum at energies just below their measurement thresholds of 2 to 3 MeV. REACTOR STUDIES OF METAL IONS ASSOCIATED WITH CHROMATOGRAPHIC SILICA Final Report
Stanley H. Langer 20 Apr. 1993 5 p
(Contract DAAL03-90-G-0123)
(AD-A266675; ARO-27600.9-CH) Avail: CASI HC A01/MF A01

Chromatographic effects from transition metal ion association with the silica used as packing materials in high-performance liquid chromatography were emphasized with special attention given to their catalytic properties and methods for studying them. Retention changes for selected solutes resulting from silica modification were also studied. For rate process analysis, a statistical method based on the first moment of the overall elution profile was developed for first-order type chemical reactions under special conditions. This approach alleviated difficulties in resolving and analyzing reactant and product overlap, and it also facilitated the study of features associated with catalysis such as adsorption. With this approach as a start and hydroquinone oxidation as a probe reaction, significant progress was made toward developing a stable, reproducible, iron(3) ion-modified silica stationary phase with considerable catalytic activity. AN INVESTIGATION OF THE ROLE OF SECOND PHASE PARTICLES IN THE DESIGN OF ULTRA HIGH STRENGTH STEELS OF IMPROVED TOUGHNESS Final Report, 1 Oct. 1989 - 31 Dec. 1992

Warren M. Garrison, Jr. 14 May 1993 34 p
(Contract DAAL03-89-K-0175)
(AD-A266774; ARO-27407.1-MS) Avail: CASI HC A03/MF A01

The influence of inclusion distributions and fine scale microstructure on the fracture toughness and fracture processes of ultra high strength steels have been investigated. The inclusion distributions vary in the sulfide type. The sulfide types considered were MnS, CrS, La2O2S, and Ti2CS. The MnS and CrS particles are smaller and more closely spaced than particles of La2O2S. Resistance to void nucleation is the same if the sulfur is gettered as CrS, MnS, or La2O2S. The particles of Ti2CS are smaller and much more resistant to void nucleation than the other sulfide types. The fine scale microstructures were those obtained for the as-quenched, tempered at 425 C and tempered at 510 C conditions for HY180 and AF1410 steels. The topics addressed are as follows: (1) effect of fine scale microstructure and inclusion distributions on blunting behavior, (2) the role of inclusion spacing at constant inclusion volume fraction on fracture toughness of three fine scale microstructures for HY 180 steel, (3) effect of gettering sulfur as Ti2CS on the fracture toughness of three fine scale microstructures of HY180 steel, (4) morphology of Ti2CS particles, (5) effect of gettering sulfur as Ti2CS on the fracture toughness of AF1410 steel tempered at 510 C, and (6) conclusions regarding improving toughness by gettering sulfur as Ti2CS. THE EFFECT OF CRYSTAL TILT ON HIGH RESOLUTION MICROGRAPHS OF SMALL METAL PARTICLES
J. O. Malm (Lund Univ., Sweden.) and M. A. OKeefe Jan. 1993 2 p Presented at the Conference on Electron Microscopy, Lund, Sweden, 9-11 Jun. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC03-76SF-00098)
(DE93-013915; LBL-33753; CONF-9306164-1) Avail: CASI HC A01

The structure of small (1.5-5 nm) metal particles has been studied by high resolution transmission electron microscopy. For particles of this size, it is not possible to use tilting techniques (selected area diffraction), which means that the microscopist has to rely on the image when deciding in which direction the particle is viewed. This work points out some of the problems of intuitive determination of the viewing direction. DOE

MICROSTRUCTURAL ORIGINS AND MODELING OF INTERGRANULAR CRACK INITIATION IN AN Al-Li-Cu-Mg-(Zr) ALLOY Ph.D. Thesis [ORIGINES MICROSTRUCTURALES ET MODELISATION DE L'AMORCAGE DES FISSURES INTERGRANULAIRES D'UN ALLIAGE AL-LI-CU-MG-(ZR)]
Catherine Bourges-Verdu 1991 239 p In FRENCH Sponsored by Centre de Recherche de Pechiney, France
(ISAL-91-0012; ETN-93-94356) Avail: CASI HC A11/MF A03

Microscopic mechanisms of intergranular fracture of Al-Li-Cu-Mg-(Zr) alloys are studied and modeled. An original experimental method was used to show that this fracture is linked to plastic deformation of the alloy. Only a single family of slip planes was observed due to the marked crystallographic texture and due to the shearing of the Al3Si precipitates. The intergranular fracture resulted principally because of the interaction with the joint grains, rectilinear and sinuous shears. The intergranular precipitation of the quasicrystalline phase T2 and the presence of a zone without Al3Li precipitates favors the initiation of intergranular cracks because of the incompatibility of plastic deformation between the T2 phase and the matrix. INFLUENCE OF HEAT TREATMENT ON MICROSTRUCTURE OF Ti-35wt Al PREPARED BY ELEMENTAL POWDER METALLURGY
G.-X. Wang and M. Dahms 1992 10 p Repr. from Scripta Metallurgica et Materialia, Elmsford, NY, Pergamon Press, v. 26, no. 5, 1992 p 712-722
(GKSS/92/E/27; ETN-93-94610) Copyright Avail: Issuring Activity (GKSS-Forschungszentrum Geesthacht G.M.B.H., D-W-2054, Geesthacht, Germany)

The hardness of the Ti-35 wt. percent Al alloy, as an indicator for mechanical properties under unidirectional loading, is investigated as a function of the microstructure obtained. The influence of heat treatment on the alloy's microstructure is analyzed. Titanium aluminide alloys based on the intermetallic compound gamma-TiAl are potential materials for high performance airframe and gas turbines. The powder mixture was pressed at room temperature and after canning in Ti tubes the samples were hot isostatically pressed. The results of the microstructure analysis showed that: the element distribution after hot isostatically pressing treatment was very homogeneous with Ti content varying from 42 to 68 atoms; four different structures can be observed; the lamellar volume fraction is strongly dependent on heat treatment. The results of microhardness tests are shown. ESA

THE GROWTH OF SHORT FATIGUE CRACKS IN AN ALUMINIUM ALLOY
R. Cook 24 Nov. 1992 50 p
(RAE-TR-92063; RAE-Mat/Str-363; ICAF-1867; BR315742; ETN-93-94500) Copyright Avail: CASI HC A03/MF A01

Fatigue tests were carried out to establish the effects of various constant amplitude and standardized variable amplitude loading sequences on the growth of short and long crack in 2024-T3 aluminum alloy. In most cases, the growth rates of short cracks were greater than those of long cracks for the same nominal stress intensity factor ranges, and short cracks grew at stress intensity factor ranges below the long crack threshold values. The experimental crack growth results are discussed and compared with predictions based on the FASTRAN crack closure model of Newman. Experimental work which represented the United Kingdom contribution to the core program of the AGARD cooperative program on short crack growth behavior is included. ESA

EFFECT OF THERMAL PROCESSING PRACTICES ON THE PROPERTIES OF SUPERPLASTIC Al-Li ALLOYS Final Report
Stephen J. Hales and Henry E. Lippard (Northwestern Univ., Evanston, IL.) Washington Sep. 1993 63 p
(Contract NAS1-19399; RTOP 505-63-50-03)
(NASA-CR-4548; NAS 1.26:4548) Avail: CASI HC A04/MF A01

The effect of thermal processing on the mechanical properties of superplastically formed structural components fabricated from three aluminum-lithium alloys was evaluated. The starting materials consisted of 8090, 2090, and X2095 (Weldalite(TM) 049), in the form of commercial-grade superplastic sheet. The experimental test matrix was designed to assess the impact on mechanical properties of eliminating solution heat treatment and/or cold water quenching from post-forming thermal processing. The extensive hardness and tensile property data compiled are presented as a function of aging temperature, superplastic strain and temper/quench rate for each alloy. The tensile properties of the materials following superplastic forming in two T5-type tempers are compared with the baseline T6 temper. The implications for simplifying thermal processing without degradation in properties are discussed on the basis of the results. Author (revised)

ANALYSIS OF SAMPLES OF REFLECTOR MATERIALS WHICH ARE MULTICOATED AND METAL SAMPLES WITH OXIDE COATINGS WHICH HAVE BEEN EXPOSED THE SPACE ENVIRONMENT IN LDEF TESTING Final Report
W. C. Neely 30 Sep. 1992 2 p
(Grant NAG1-1313)
(NASA-CR-193647; NAS 1.26:193647) Avail: CASI HC A01/MF A01

The use of low angle x-ray diffraction (XRD), x-ray photoelectron spectrometry (XPS), and Auger spectrometry have been tested as suitable methods for analysis of thin oxide films on metal substrates exposed to the space environment during Long Duration Exposure Facility (LDEF) testing. No significant changes in the composition of silicon monoxide overcoats on aluminum surfaces was found. XPS and Auger testing appear to be more suitable for ultrathin films than XRD. SYSTEM INTEGRATION AND DEMONSTRATION OF ADHESIVE BONDED HIGH TEMPERATURE ALUMINUM ALLOYS FOR AEROSPACE STRUCTURE, PHASE 2 Final Report
Anthony Falcone and John H. Laakso Jul. 1993 108 p
(Contract NAS1-18560; RTOP 505-63-20-01)
(NASA-CR-191459; NAS 1.26:191459; D658-10313-1) Avail: CASI HC A06/MF A02

Adhesive bonding materials and processes were evaluated for assembly of future high-temperature aluminum alloy structural components such as may be used in high-speed civil transport aircraft and space launch vehicles. A number of candidate high-temperature adhesives were selected and screening tests were conducted using single lap shear specimens. The selected adhesives were then used to bond sandwich (titanium core) test specimens, adhesive toughness test specimens, and isothermally aged lap shear specimens. Moderate-to-high lap shear strengths were obtained from bonded high-temperature aluminum and silicon carbide particulate-reinforced (SiC(sub p)) aluminum specimens. Shear strengths typically exceeded 3500 to 4000 lb/in(sup 2) and flatwise tensile strengths exceeded 750 lb/in(sup 2) even at elevated temperatures (300 F) using a bismaleimide adhesive. All faceskin-to-core bonds displayed excellent tear strength. The existing production phosphoric acid anodize surface preparation process developed at Boeing was used, and gave good performance with all of the aluminum and silicon carbide particulate-reinforced aluminum alloys investigated. The results of this program support using bonded assemblies of high-temperature aluminum components in applications where bonding is often used (e.g., secondary structures and tear stoppers). ELECTROPHORETIC AND ELECTROLYTIC DEPOSITION OF CERAMIC PARTICLES ON POROUS SUBSTRATES Final Report, 1 Mar. 1988 - 30 Nov. 1992
L. Gal-Or, S. Haber, and S. Liubovich 30 Sep. 1992 278 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0474-89)
(AD-A265141; AFOSR-93-0344TR) Avail: CASI HC A13

Electrophoretic deposition of ceramic particles and their penetration into the pores of graphite and a 2D C-C composite were demonstrated and studied theoretically and experimentally for colloidal SiO2, SiC, Si3N4, Al2TiOs and HfTiO4. The effect of deposition parameters (field intensity, particle concentration, and ratio of dielectric constant/viscosity of fluid) on the amount of induced material was experimentally studied. Penetration depth of particles as function of the above parameters was analyzed theoretically. Penetration is enhanced by large Peclet numbers and is higher in aqueous suspensions, while coating morphology is better in propanol suspensions. Optimal conditions for coverage and penetration in a two-stage process were determined. Subsequent deposition of two layers was demonstrated and studied for Si3N4 on Al2TiO5 and SiC on a glass ceramic. Single (Si3Ni4, Al2TiO5, and HfTiO4) and multilayer (Si3N4 on Al2TiO5, and Si3N4 on fused SiO2) coatings were deposited, sintered in a N2 atmosphere, and their phase composition and morphology studied. Oxidation resistance of coated specimens was studied at 830 C in continuous and intermittent exposures. Graphite exhaust nozzles were coated and tested in an air breathing engine simulation. Very efficient protection was achieved. Electrolytic deposition of ZrO2, Al2O3, and Al2O3+ZrO2 was achieved from aqueous solutions of ZrO(NO3)2 and Al(NO3)3. The deposition kinetics and microstructure of the deposits were studied. The initial amorphous deposits transformed into crystalline phases with monocrystalline dimensions after heat treatment. DTIC

THEORETICAL TREATMENT OF THE BULK AND SURFACE PROPERTIES OF FLUIDS CONTAINING LONG, FLEXIBLE MOLECULES
1993 5 p
(Contract DE-FG05-91ER-14181)
(DE93-015560; DOE/ER-14181/1) Avail: CASI HC A01/MF A01

The purpose is to develop an equation of state for predicting the thermodynamic properties of fluids containing chain-like molecules ranging from alkanes to polymers. Foundation of this work is the Generalized Flory Dimer (GFD) theory. GFD is extended to square-well chain mixtures. The second virial coefficient has been evaluated for hard-chain and square-well chain fluids using a Monte Carlo approach. The polymer RISM theory was used to determine the segment-segment radial distribution function for hard chain fluids. Monte Carlo simulations are being performed of the self-diffusion

coefficient, shear and longitudinalviscosities, and thermal conductivity for hard chain fluids. DOE

AMORPHOUS SOL-GEL INSULATING FILMS
C. J. Brinker (New Mexico Univ., Albuquerque.), W. L. Warren, M. N. Logan, and C. S. Ashley 1993 12 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC04-76DP-00789)
(DE93-012859; SAND-93-0582C; CONF-921101-114) Avail: CASI HC A03/MF A01

The porosity of sol-gel thin films may be tailored for specific applications through control of the size and structure of inorganic polymers within the coating sol, the extent of polymer reaction and interpenetration during film formation, and the magnitude of the capillary pressure exerted during the final stage of drying. By maximizing the capillary pressure and avoiding excessive condensation, dense insulating films may be prepared as passivation layers on silicon substrates. Such films can exhibit excellent dielectric integrity, viz., low interface trap densities and insulating properties approaching those of thermally grown SiO2. Alternatively, through exploitation of the scaling relationship of mass and density of fractal objects, silica films can be prepared that show a variation in porosity (7-29 percent) and refractive index (1.42-1.31) desired for applications in sensors, membranes, and photonics. RECOVERY OF MATERIALS IMPACTED AT HIGH VELOCITY
W. J. Nellis and A. J. Gratz Dec. 1992 11 p Presented at the Hypervelocity Impact Symposium, Austin, TX, 17-20 Nov. 1992
(Contract W-7405-eng-48)
(DE93-014150; UCRL-JC-110081; CONF-921162-16) Avail: CASI HC A03/MF A01

Hypervelocity impact can produce unique effects in materials including crystal structures, microstructures, and properties. Examples include impact-driven shock waves to synthesize novel materials--1 mm and 1 micron thin--shocked to pressures up to 100 GPa (1 Mbar), preferential crystallographic alignment achieved by taking into account the shape and size of powder particles, and high-pressure phase transitions quenched in geological materials. Thin specimens are used to achieve the highest quench rates. Methods are described which show that the experiments can be performed by precooling or preheating specimens in the range -170 to +1000 C. Calculational results for the quartz experiments show the importance of computational simulations to determine the pressure history in the specimen. DOE

CORRELATIONS OF THE GROWTH, STRUCTURE, AND STRESS WITH THE ADHESION OF DIAMOND FILMS ON TUNGSTEN
M. Alam (New Mexico Inst. of Mining and Technology, Socorro.), D. E. Peebles, D. R. Tallant, and J. A. Ohlhausen 1993 17 p Presented at the International Conference on Metallurgical Coatings and Thin Films, San Diego, CA, 19-23 Apr. 1993
(Contract DE-AC04-76DP-00789)
(DE93-012855; SAND-93-0826C; CONF-930419-1) Avail: CASI HC A03/MF A01

Diamond films were deposited on tungsten substrates by a filament-assisted chemical vapor deposition process as a function of seven different processing parameters. The effect of variations in measured film characteristics such as growth rate, texture, diamond-to-nondiamond carbon Raman band intensity ratio and strain on the adhesion between the diamond film/tungsten substrate pairs as measured by a tensile pull method were investigated. The measured adhesion values do not correlate with any of the measured film characteristics mentioned above. The problem arises because of the non-reproducibility of the adhesion test results, due to the non-uniformity of film thickness, surface preparation and structural homogeneity across the full area of the substrate. DOE

N94-12916# Los Alamos National Lab., NM.
CERAMIC MATRIX COMPOSITES BY MICROWAVE ASSISTED CVI
R. P. Currier and D. J. Devlin 1993 11 p Presented at the 95th Annual Meeting of the Americdan Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract W-7405-eng-36)
(DE93-012640; LA-UR-93-1322; CONF-930438-14) Avail: CASI HC A03/MF A01

Chemical vapor infiltration (CVI) processes for producing continuously reinforced ceramic composites are reviewed. The potential advantages of microwave assisted CVI are noted. Recent numerical studies of microwave assisted CVI are then reviewed. These studies predict inverted thermal gradients in fibrous ceramic preforms subjected to microwave radiation and suggest processing strategies for achieving uniformly dense composites. Comparisons are made to experimental results obtained using silicon based composite systems. The importance of microwave-material interactions is stressed. In particular, emphasis is placed on the role played by the relative ability of fiber and matrix to dissipate microwave energy. Results suggest that microwave induced inverted gradients can in fact be exploited using the CVI technique to promote inside-out densification. DOE

MODELING THE IMPACT BEHAVIOR OF AD85 CERAMIC UNDER MULTI-AXIAL LOADING Final Report
A. M. Rajendran May 1993 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A265877; ARL-TR-137) Avail: CASI HC A03

This report presents an advanced constitutive model to describe the complex behavior of ceramic materials under impact loading conditions. The governing equations utilize a set of microphysically based constitutive relationships to model deformation and damage processes in a ceramic. The total strain is decomposed into elastic, plastic, and microcracking components. The model parameters for the AD85 ceramic were determined using the data from split Hopkinson bar (SHB) and bar-on-bar experiments under uniaxial stress state and plate impact experiment under uniaxial strain state. To further validate the generality of the model parameters, modeling of a diagnostic ballistic experiment in which a steel projectile impacted an AD85 ceramic front-faced thick aluminum plate was considered. In this experiment, stress histories were measured in the target by embedded manganin and carbon stress gauges. The results from the numerical simulations of the ballistic experiment, using a shock wave propagation based finite element code, successfully matched the measured stress history. Author (DTIC)

PROJECT PROPOSAL FOR PARTIAL COMPUTATIONAL PHYSICS SUPPORT FOR SURVIVABILITY OF COATINGS PROGRAM
C. E. Rhoades, Jr. Mar. 1993 10 p
(Contract W-7405-eng-48)
(DE93-013788; UCRL-ID-113715) Avail: CASI HC A02/MF A01

Currently, the Survivability of Coatings (SOC) program uses the XRT computer code to calculate the effects of X-rays of various spectra on mirrors consisting of one or more optical coatings of specified thicknesses over various substrates. The following physical processes are modeled by XRT in one spatial dimension: (1) X-ray deposition and transport, (2) electron production, deposition and transport, (3) thermal conduction and transport, and (4) resulting static and dynamic stress and deformation. In general, the numerical techniques used in XRT are deterministic ones: X-ray transport

is handled by multigroup discrete ordinates, electron transport is performed by the method of characteristics applied to a two term spherical harmonics expansion approximation (PI) of the Spencer-Lewis transport equations, and thermal transport is done by a simple Richardson extrapolation of a backward Euler solution to the heat conduction equation. XRT has been used for both preshot and postshot analyses of samples for both aboveground tests (AGT) and underground tests (UGT). Agreement of analyses with experiment has been reasonably good. However, several samples predicted not to fail did appear to be damaged in a recent UGT. In addition, at least one sample predicted to fail did not. Preliminary analysis of the experimental samples on the recent AGT performed at Maxwell Laboratories in San Diego for the SOC program shows similar difficulties. DOE

CHARACTERIZATION OF 1:1 RANDOM COPOLYMERS OBTAINED FROM 6-, 7-, 11-, AND 12-CARBON AMINO ACIDS Technical Report, 1 Jun. 1992 - 31 May 1993

C. G. Johnson and Lon J. Mathias 7 Jun. 1993 27 p

(Contract N00014-89-J-1225)

(AD-A265827; TR-55) Avail: CASI HC A03/MF A01

Copolymers were prepared from the title amino acids by melt condensation under dry nitrogen. The resulting copolymers were characterized by solution and solid-state NMR, FTIR, DSC, and WAXD. Solution NMR spectra (at 75.5 MHz) showed multiple peaks with almost equal intensities in the carbonyl region (indicating random copolymer formation) with no evidence of end-group peaks (confirming high molecular weight). Solid-state C-13 (at 100.6 MHz) and N-15 (at 20.3 MHz) spectra of most solution cast films contained peaks consistent with the gamma-form crystallites (delta(sub N-15) ca 89) being the predominant ordered phase. Only nylon 6-co-7 formed almost exclusive alpha-form on soiution casting (delta(sub N-15) 84.5). Nylon 7-co-11 formed the alpha-form almost exclusively from the melt but gave a combination of alpha- and gamma-phases (delta(sub N-15) 84.5 and 88.7) on solution casting. The copolymers possessed 3-component C-13 T(sub 1) values ranging from 21 to 97 s for the slowest-relaxing component, indicating less-ordered domains than for the homopolymers. DTIC

UNEXPECTEDLY RAPID HYDROSILATION POLYMERIZATION OF THE DIALLYL DERIVATIVE OF BISPHENOL A AND 2,6-DIALLYLPHENOL Technical Report, 1 Jun. 1992 - 31 May 1993

Lon J. Mathias and Charles M. Lewis 7 Jun. 1993 14 p

(Contract N00014-89-J-1225)

(AD-A265832; TR-51) Avail: CASI HC A03/MF A01

Several members of a novel family of reactive oligomers and polymers have been synthesized using the hydrosilation polyaddition of 1,1,3,3-tetramethyldisiloxane and 1,1,3,3,5,5-hexa-methyltrisiloxane with the 2,2'-diallyl derivative of bisphenol A (BPA) or 2,6-diallylphenol. Polymerization occurred much faster than that observed for any other hydrosilation reaction of which we are aware: while a typical hydrosilation takes minutes to hours to complete with catalytic amounts of various platinum catalysts, and most unprotected functional groups inhibit the addition, reactions of 2-allylphenol moieties occur virtually instantaneously. In fact, reactions of the diallyl monomers listed must be cooled to prevent explosive loss of reagents from the reaction vessel; even then, thermal loss of the silane monomers can disrupt stoichiometric balance. With cooling, good yields of polymers were obtained which possess excellent solubility in virtually all organic solvents and intrinsic viscosity values of 0.21-0.23 dL/g. DTIC

DEVELOPMENT OF NONDESTRUCTIVE EVALUATION METHODS AND PREDICTION OF EFFECTS OF FLAWS ON THE FRACTURE BEHAVIOR OF STRUCTURAL CERAMICS

W. A. Ellingson, J. P. Singh, D. L. Holloway, S. L. Dieckman, D. Singh, and E. A. Sivers Mar. 1993 12 p Presented at the 7th Annual Conference on Fossil Energy Materials, Oak Ridge, TN, 11-13 May 1993

(Contract W-31-109-eng-38)

(DE93-012942; ANL/MCT/CP-79029; CONF-9305135-3) Avail: CASI HC A03/MF A01

Work emphasized continuous-fiber ceramic matrix composites (CFCC's) with 2-D lay-ups composed of chemical-vapor-infiltrated (CVI) SiC/SiC materials, mostly made of Nicalon plain weave with 16 x 16 tows/in. One sample examined comprised a 3-D SiC/SiC braid made by Techniweave. Using a new 1024 x 1024 x 14 bit detector, images from 3-D X-ray CT data with pixel sizes of less than 140 microns and 2-D fast-Fourier transform (FFT) image processing, we have shown that fiber orientations can be measured to plusminus 2-1/2 deg. 3-D FFT analysis was used to determine 3-D braid/weave fiber spacing. Multinuclear (H-1, C-13, and SI-29) NMR spectroscopy, is being studied. Surface chemistry of fibers and chemistry of interfacial regions in composites are being studied. We are also conducting initial studies to investigate the bulk composition of matrix materials (alpha, beta, amorphous phase, silica, and oxynitride concentration) and surface chemistry of Si3N4 and SiC fibers. Fracture mechanics work to correlate with NDE data focused on strength distribution of as-fabricated Nicalon fibers obtained from bundle tests. Strength distribution of fractured Nicalon fibers in composites was assessed from fracture mirror radii. SEM was used to determine distribution of fiber pullout length distribution for fibers in composites, for their strength distribution. From the strength distribution plots, scale parameters were determined to be 3.45 GPa for as-fabricated fibers and 1.31 GPa for fibers in processed composites. However, the Weibull moduli for the two distributions were similar. Reduction in strength of the fibers in processed composites is believed to be due to surface flaws and defects. Effects of fiber misorientation on mechanical properties of NDE-tested CVI continuous-fiber composites are currently being investigated. DOE

COMPUTER SIMULATIONS FOR THE ADSORPTION OF POLYMERS ONTO SURFACES

A. C. Balazs 1993 13 p

(Contract DE-FG02-90ER-45438)

(DE93-016667; DOE/ER-45438/3) Avail: CASI HC A03/MF A01

Polymer-surface interactions are important in every stage of oil and coal production, production of new energy-efficient composite materials, and in medicine. Therefore, it is important to isolate the factors that influence the interfacial activity of polymer chains. We developed theoretical models and computer simulations to determine effects of polymer architecture, solvent quality, and surface morphology on properties of chains at penetrable and impenetrable interfaces. RESEARCH ON CHEMICAL VAPOR DEPOSITION PROCESSES FOR ADVANCED CERAMIC COATINGS Final Technical Report, 1 Mar. 1988 - 1 Nov. 1992

Daniel E. Rosner Jan. 1993 24 p

(Grant NAG3-884)

(NASA-CR-193613; NAS 1.26:193613) Avail: CASI HC A03/MF A01

Our interdisciplinary background and fundamentally-oriented studies of the laws governing multi-component chemical vapor deposition (VD), particle deposition (PD), and their interactions, put the Yale University HTCRE Laboratory in a unique position to significantly advance the 'state-of-the-art' of chemical vapor deposition (CVD) R&D. With NASA-Lewis RC financial support, we initiated a program in March of 1988 that has led to the advances described in this report (Section 2) in predicting chemical vapor transport in high temperature systems relevant to the fabrication of refractory ceramic coatings for turbine engine components. This Final Report covers our principal results and activities for the total NASA grant of $190,000.

over the 4.67 year period: 1 March 1988-1 November 1992. Since our methods and the technical details are contained in the publications listed (9 Abstracts are given as Appendices) our emphasis here is on broad conclusions/implications and administrative data, including personnel, talks, interactions with industry, and some known applications of our work.

DRY FILM LUBRICANT EVALUATION
R. M. Bryan Apr. 1993 15 p
(Contract DE-AC04-76DP-00613)
(DE93-013114; KCP-613-5044) Avail: CASI HC A03/MF A01

The lubrication characteristics of a modified tungsten disulfide (WS2) were compared to the existing dry film lubricant, a molybdenum disulfide (MoS2). WS2 was verified as meeting all Environment, Safety, and Health (ES&H) requirements for a replacement dry film lubricant. However, in life and wear characteristics, the present lubricant outperformed the WS2. Two studies to determine if welding could be performed through the WS2 coating indicated functionally strong welds, but evaluation showed cracks which would not meet weld requirements. Bearing tests comparing WS2, a low molecular weight tetrafluoroethylene (TFE), and unlubricated bearings indicated that WS2 bearing torque was 70 percent higher than TFE. DOE

SCANNING TUNNELING MICROSCOPY STUDIES OF DIAMOND FILMS AND OPTOELECTRONIC MATERIALS Progress Report, 1 Dec. 1992 - 1 Oct. 1993
Jose M. Perez 1993 20 p Original contains color illustrations
(Grant NAG1-1468)
(NASA-CR-194363; NAS 1.26:194363) Avail: CASI HC A03/MF A01; 3 functional color pages

In this report, we report on progress achieved from 12/1/92 to 10/1/93 under the grant entitled 'Scanning Tunneling Microscopy Studies of Diamond Films and Optoelectronic Materials'. We have set-up a chemical vapor deposition (CVD) diamond film growth system and a Raman spectroscopy system to study the nucleation and growth of diamond films with atomic resolution using scanning tunneling microscopy (STM). A unique feature of the diamond film growth system is that diamond films can be transferred directly to the ultrahigh vacuum (UHV) chamber of a scanning tunneling microscope without contaminating the films by exposure to air. The University of North Texas (UNT) provided $20,000 this year as matching funds for the NASA grant to purchase the diamond growth system. In addition, UNT provided a Coherent Innova 90S Argon ion laser, a Spex 1404 double spectrometer, and a Newport optical table costing $90,000 to set-up the Raman spectroscopy system. The CVD diamond growth system and Raman spectroscopy system will be used to grow and characterize diamond films with atomic resolution using STM as described in our proposal. One full-time graduate student and one full-time undergraduate student are supported under this grant. In addition, several graduate and undergraduate students were supported during the summer to assist in setting-up the diamond growth and Raman spectroscopy systems. We have obtained research results concerning STM of the structural and electronic properties of CVD grown diamond films, and STM and scanning tunneling spectroscopy of carbon nanotubes. In collaboration with the transmission electron microscopy (TEM) group at UNT, we have also obtained results concerning the optoelectronic material siloxene. These results were published in refereed scientific journals, submitted for publication, and presented as invited and contributed talks at scientific conferences. Derived from text

SURFACES AND INTERFACES OF CERAMICS AND METALS
1992 16 p
(Contract DE-FG02-86ER-45228)
(DE93-014959; DOE/ER-45228/65) Avail: CASI HC A03/MF A01

Structures of surfaces of several ceramic oxides were studied by use of reflection electron microscopy (REM) and associated techniques. High-temperature annealing in air or oxygen gives smooth, flat crystal faces in most cases, including the (111) MgO surface, previously thought to be facetted. Stability of the (111) MgO surface is shown to be due to a surface superlattice reconstruction. Surface superlattices, stable in air, have also been shown to exist on sapphire and rutile crystal faces. The segregation of Ca to the surface of MgO has been studied using reflection electron energy loss techniques. Initial studies of Cu-Au alloy crystal surfaces, necessarily carried out in ultra-high vacuum, have been made using RHEED and Auger electron spectroscopy. Clean alloy surfaces show surface reconstructions associated with the segregation of Au atoms at the surface. High-temperature annealing results in the segregation of sulfur to the surface and the formation of a variety of surface superlattice structures. Structures of solid-solid interfaces have been studied using a wide variety of electron-optical techniques including nanodiffraction and electron holography. In particular, the interfaces in semiconductor multiple quantum well structures and also multilayer structures of Si and Co have been studied. DOE

HIGH TEMPERATURE ELECTROMAGNETIC CHARACTERIZATION OF THERMAL PROTECTION SYSTEM TILE MATERIALS Final Report
Garrett G. Heil Sep. 1993 138 p
(Contract NAS1-18763; RTOP 592-01-11-12)
(NASA-CR-189687; NAS 1.26:189687; MDC-92B0034) Avail: CASI HC A07/MF A02

This study investigated the impact of elevated temperatures on the electromagnetic performance of the LI-2200 thermal protection system. A 15-kilowatt CO2 laser was used to heat an LI-2200 specimen to 3000 F while electromagnetic measurements were performed over the frequency range of l9 to 21 GHz. The electromagnetic measurement system consisted of two Dual-Lens Spot-Focusing (DLSF) antennas, a sample support structure, and an HP-8510B vector network analyzer. Calibration of the electromagnetic system was accomplished with a Transmission-Reflection-Line (TRL) procedure and was verified with measurements on a two-layer specimen of known properties. The results of testing indicated that the LI-2200 system's electromagnetic performance is slightly temperature dependent at temperatures up to 3000 F.

THERMODIFFUSION IN HETEROGENEOUS ELASTIC SOLIDS AND HOMOGENIZATION
A. Galka, J. J. Telega, and R. Wojnar 1993 77 p
(Rept-14/1993) Avail: CASI HC A05/MF A01

Overall behavior of microheterogeneous elastic solids in which thermodiffusion occurs is studied by using homogenization methods. Heterogeneities are characterized by a small positive parameter epsilon. The material coefficients of the coupled system of linear equations describing thermodiffusion depend on epsilon. In the periodic case, when heterogeneities are distributed periodically, the homogenization is performed by applying the method of two-scale asymptotic expansions. The convergence and corrector theorems are formulated for a nonperiodic microstructure. It is shown that the initial conditions for the temperature and chemical potential of the homogenized system are changed in comparison with the primal one provided that the initial conditions for the latter system are nonhomogenous. For a layered composite with periodically distributed layers analytical formulas are derived for all the effective material coefficients. Particular cases are studied by exploiting some available experimental data. The analysis itself and homogenization problem are preceded by an overview of the results concerning thermal problems in microheterogeneous solids and composites. Author (revised)

CANONICAL CORRELATION OF WASTE GLASS COMPOSITIONS AND DURABILITY, INCLUDING pH
D. Oeksoy, L. D. Pye (Alfred Univ., NY.), D. F. Bickford, and W. G. Ramsey 1993 16 p Presented at the 95th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract DE-AC09-89SR-18035)
(DE93-012754; WSRC-MS-93-222; CONF-930438-8) Avail: CASI HC A03/MF A01

Control of waste glass durability is a major concern in the immobilization of radioactive and mixed wastes. Leaching rate in standardized laboratory tests is being used as a demonstration of consistency of the response of waste glasses in the final disposal environment. The leaching of silicate and borosilicate glasses containing alkali or alkaline earth elements is known to be autocatalytic, in that the initial ion exchange of alkali in the glass for hydrogen ions in water results in the formation of OH and

increases the pH of the leachate. The increased pH then increases the rate of silicate network attack, accelerating the leaching effect. In well formulated glasses this effect reaches a thermodynamic equilibrium when leachate saturation of a critical species, such as silica, or a dynamic equilibrium is reached when the pH shift caused by incremental leaching has negligible effect on pH. This report analyzes results of a seven leach test on waste glasses. DOE

POLING OF THIN POLYMER FILMS IN ELECTRO OPTIC APPLICATIONS Final Report, 1 Apr. 1990 - 30 Mar. 1993
Gerald G. Fuller 8 Jun. 1993 2 p
(Contract DAAL03-90-G-0081)
(AD-A266562; ARO-26883.2-MS) Avail: CASI HC A01/MF A01

Many polymeric glasses must be orientationally ordered for the materials to exhibit useful characteristics. The objective of this work was to understand the dynamics of the orientation and relaxation processes and to relate these behaviors to the structural characteristics of the polymeric material. In this study we considered materials suitable for nonlinear optical applications. In particular, thin polymer films, either doped with nonlinear optical chromophores or films with the chromophores covalently bonded to side groups were studied. Orientation of these chromophores was achieved by the birefringence resulting from chromophore concentration, spacer length, and molecular dominant factor determining the steady state and transient behaviors. The relationship between monomer and polymer structure and the resulting effect on the orientation dynamics is discussed. Qualitative agreement with theoretical predictions was obtained for the simpler guest/host system, but the model was shown to be inadequate to explain the behaviors of the more complex systems studied. The results reported here have provided valuable insight into the molecular processes that occur during the chromophore orientation and relaxation and the effects of structural characteristics of the polymers on these mechanisms. APPLICATIONS OF SURFACE SCIENCE TO SOLID LUBRICANTS
Stephen V. Didziulis and Paul D. Fleischauer 15 Mar. 1993 55 p
(Contract F04701-88-C-0089)
(SMC-TR-93-24; TR-93(3935)-4; AD-A267563) Avail: CASI HC A04/MF A01

Solid lubricants fill a very important niche in the world of tribology by providing low-friction surfaces under harsh operating conditions, such as high or very low temperature and high vacuum. The successful use of solid lubricants in most applications relies on controlling the chemical interactions occurring at several interfaces, and the use of surface science techniques to study and understand these chemical interactions has become increasingly more important in recent years. In this report, the surface properties of molybdenum disulfide (MoS2), the most widely used solid lubricant for space applications, are studied with a variety of techniques. The techniques discussed are: valence band photoelectron spectroscopy (PES) to determine electronic structure properties; scanning tunneling and atomic force microscopies to examine surface structure; high-resolution electron energy loss spectroscopy to determine surface phonon properties; core level PES with synchrotron radiation to study metal/MoS2 interfacial chemistry; core level x-ray photoelectron spectroscopy to study steel and ceramic substrate chemistry; and extended x-ray absorption fine structure, electron microscopies, and x-ray diffraction to study film structure. In addition, theoretical and tribological studies of MoS2 are discussed. The goal of this work is to develop a fundamental understanding of the electronic structure and reactivity of MoS2 as determined by these surface science techniques, and to relate this fundamental understanding to the performance of MoS2 as a solid lubricant. Vickers hardness measurement with the finite element method is simulated. Calculations were performed for homogeneous specimen materials and for film systems from core material and surface film. Three dimensional and two dimensional models with finite elements of indentation processes on the basis of different test body models were realized for calculation of mechanical reaction of laminate systems to external loading due to sharp test bodies. Strains and stresses at impact location, indentation depth in the specimen surface and material hardness as a function of applied force were calculated. Numerical results for elastic materials were estimated by comparison with analytical solutions. Simulation results for elastic-plastic materials were compared with experimental data. Relative influence of test

machine and specimen parameters was discussed. Friction influence in contact area between specimen and test body for sharp and round bodies was simulated. Material effects on indentation behavior was examined by variation of specimen parameters. ESA

LASER-DAMAGE SUSCEPTIBILITY OF NODULAR DEFECTS IN DIELECTRIC MIRROR COATINGS: AFM MEASUREMENTS AND ELECTRIC-FIELD MODELING
M. R. Kozlowski, J. F. DeFord, and M. C. Staggs 15 Apr. 1993 6 p Presented at the 2nd International Conference on Laser Ablation, Knoxville, TN, 19-22 Apr. 1993
(Contract W-7405-eng-48)
(DE93-014655; UCRL-JC-112981; CONF-9304144-1) Avail: CASI HC A02/MF A01

Atomic force microscopy (AFM) and electromagnetic field modeling were used to study the influence of nodular coating defects on laser-induced damage of multilayer dielectric coatings. In studies of HfO2/SiO2 mirrors with 1.06 microns illumination, AFM results showed that nodular defects with high dome heights (greater than 0.6 microns) were most susceptible to laser damage. Crater defects, formed by nodules ejected from the coating prior to illumination, were not damaged when illuminated over the same range of fluences. A finite-difference time-domain electromagnetic modeling code was used to study the influence of 3-D nodule defects on the E-field distribution within the interference coating. The modeling results show that E-field enhancements as large as a factor of 4 can be present at the defects. Crater defects, however, result in minimal enhancement of the E-fields within the coating. These modeling results are consistent with the AFM experimental data, indicating that E-field enhancement is a contributing mechanism in defect-dominated laser damage of optical coatings. DOE

SYNTHETIC LUBRICANTS AND HIGH-PERFORMANCE FUNCTIONAL FLUIDS: PHOSPHAZENES Final Report
Robert E. Singler and Mary Jo Bieberich (Naval Surface Warfare Center, Annapolis, MD.) Jan. 1993 18 p Repr. from Synthetic Lubricants and High Performance Functional Fluids: Phosphazenes, Chapter 10, 1992 p 215-228
(ARL-TR-45) Avail: CASI HC A03/MF A01

The synthesis, properties, and development of phosphazene fluids are reviewed, with an emphasis on military applications. Most of their search and development of phosphazene fluids has centered on the alkoxy- and aryloxycyclophosphazenes for fire-resistant, compression-ignition-resistant hydraulic fluids to meet requirements for MIL-H-19457. Related developments include applications such as high temperature lubricants for aircraft gas turbine engines, lubricity additives, applications in the electronic industry, fire-resistant additives, vacuum pump oil, and electrorheological fluids. Chemical compositions, physical properties, lubricity data, and toxicity information are given, along with projected costs for high volume use applications. Currently, some phosphazene fluids are commercially available in small quantities. Author

SPIN POLARIZED PHOTOEMISSION STUDIES OF INTERFACIAL AND THIN FILM MAGNETISM
P. D. Johnson, N. B. Brookes, Y. Chang, and K. Garrison 1993 10 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract DE-AC02-76CH-00016)
(DE93-014326; BNL-48953; CONF-930405-13) Avail: CASI HC A02/MF A01

Spin polarized photoemission is used to study the electronic structure of noble metals deposited on ferromagnetic substrates. Studies of Ag deposited on an Fe(001) substrate reveal a series of minority spin interface or quantum well states with binding energies dependent on the thickness of the silver. Similar behavior is observed for Cu films deposited on a fct Co(001) substrate. Tight-binding modeling reproduces many of the observations and shows that hybridization of the sp-bands with the noble metal d-bands cannot be ignored. DOE

SCHEMES FOR THE USE OF CONDUCTING POLYMERS AS ACTIVE MATERIALS IN ELECTROCHEMICAL SUPERCAPACITORS
A. Rudge, J. Davey, S. Gottesfeld, and J. P. Ferraris 1993 13 p Presented at the 183rd Electrochemical Society Meeting, Honolulu, HI, 16-21 May 1993
(Contract W-7405-eng-36)
(DE93-012713; LA-UR-93-1618; CONF-930571-14) Avail: CASI HC A03/MF A01

The development of a novel conducting polymer based system for use in electrochemical capacitors is described. This system utilizes a new conducting polymer, poly-3-(4-fluorophenyl)-thiophene (PFPT), that can be reversibly n- and p-doped to high charge density. The electrochemical n-dopability of this material can be further improved by cycling in an acetonitrile solution that contains a new electrolyte, tetramethylammonium trifluoromethanesulfonate (Me4NCF3SO3). We discuss these improvements in n-dopability in terms of potential electronic and steric influences. We believe that the substituent fluorophenyl group does not communicate with the polythiophene backbone through resonance, and conclude that the ability to n-dope PFPT to high charge density may occur as a result of electron transfer reactions from the conducting polymer backbone into the substituent. This new system for electrochemical capacitors provides the best achievable performance from conducting polymers and generates high energy and power densities that are comparable with noble metal oxide systems, potentially at a fraction of the cost. SEQUESTERING CARBON DIOXIDE IN INDUSTRIAL POLYMERS: BUILDING MATERIALS FOR THE 21ST CENTURY
P. M. Molton and D. A. Nelson Jun. 1993 25 p
(Contract DE-AC06-76RL-01830)
(DE93-016087; PNL-SA-22528) Avail: CASI HC A03/MF A01

This study was undertaken to determine the possibility of developing beneficial uses for carbon dioxide as a key component for a large-volume building product. Such a use may provide an alternative to storing the gas in oceanic sinks or clathrates as a way to slow the rate of global warming. The authors investigated the concept that carbon dioxide might be used with other chemicals to make carbon-dioxide-based polymers which would be lightweight, strong, and economical alternatives to some types of wood and silica-based building materials. As a construction-grade material, carbon dioxide would be fixed in a solid, useful form where it would not contribute to global warming. With the probable imposition of a fuel carbon tax in industrialized countries, this alternative would allow beneficial use of the carbon dioxide and could remove it from the tax basis if legislation were structured appropriately. Hence, there would be an economic driver towards the use of carbon-dioxide-based polymers which would enhance their future applications. Information was obtained through literature searches and personal contacts on carbon dioxide polymers which showed that the concept (1) is technically feasible, (2) is economically defensible, and (3) has an existing industrial infrastructure which could logically develop it. The technology exists for production of building materials which are strong enough for use by industry and which contain up to 90% by weight of carbon dioxide, both chemically and physically bound. A significant side-benefit of using this material would be that it is self-extinguishing in case of fire. This report is the first stage in the investigation. Further work being proposed will provide details on costs, specific applications and volumes, and potential impacts of this technology. DOE

FORMATION OF TEXTURED YBCO FILMS BY LASER ABLATION
A. F. Jankowski and B. L. Olsen Nov. 1992 12 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract W-7405-eng-48)
(DE93-013131; UCRL-JC-111025; CONF-921101-118) Avail: CASI HC A03/MF A01

Yttrium-Barium-Cooper-Oxide (YBCO) thin films are prepared using laser ablation. The (100) orientation of the 0.2-0.3 micron thin film is controlled using both substrate temperature and deposited buffer layers for epitaxial growth. Highly textured films are prepared with a c-axis preferred orientation using substrates of SrTiO3 (100) and MgO (100) at a temperature of 780 C whereas a,b-axis films result if a 100nm buffer of Praseodymium- Barium-Copper- Oxide is first deposited at 700 C. The use of a 15nm buffer layer of SrTiO3 on MgO (100) produces films with superconducting transitions equivalent to those YBCO films deposited directly on SrTiO3 (100) substrates. DOE

MICROWAVE HYBRID HEATING OF ALUMINA FILAMENTS
G. J. Vogt and W. P. Unruh 1993 14 p Presented at the 95th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract W-7405-eng-36)
(DE93-012642; LA-UR-93-1306; CONF-930438-9) Avail: CASI HC A03/MF A01

Low loss oxide ceramics filaments are not readily heated to sintering temperatures (greater than 900 C) by direct microwave heating at 2.45 GHz. Use of high power levels typically yields thermal runaway with catastrophic melting. In other studies, hybrid, or indirect, heating has been successfully applied to processing bulk oxide ceramics. In this work, commercial alumina-based filaments have been indirectly heated to 700 - 900 C through a lossy carbon coating on the filament tow. Specific filaments can reach higher temperatures by direct coupling after preheating with a lossy coating. The results of microwave hybrid heating in a single mode TE(sub 102) cavity will be described for commercial alumina-based filaments. DOE

MICROWAVE SINTERING OF LARGE ALUMINA BODIES
R. D. Blake and J. D. Katz 1993 9 p Presented at the 95th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract W-7405-eng-36)
(DE93-012752; LA-UR-93-1456; CONF-930438-6) Avail: CASI HC A02/MF A01

The application of microwaves as an energy source for materials processing of large alumina bodies at elevated temperatures has been limited to date. Most work has concerned itself with small laboratory samples. The nonuniformity of the microwave field within a cavity subjects large alumina bodies to areas of concentrated energy, resulting in uneven heating and subsequent cracking. Smaller bodies are not significantly affected by field nonuniformity due to their smaller mass. This work will demonstrate a method for microwave sintering of large alumina bodies while maintaining their structural integrity. Several alumina configurations were successfully sintered using a method which creates an artificial field or environment within the microwave cavity. DOE

RELATIONSHIP BETWEEN BOROSILICATE GLASS COMPOSITION, STRUCTURE, AND DURABILITY TEST RESPONSE (SRS)
W. G. Ramsey, C. M. Jantzen, and T. D. Taylor (Clemson Univ., SC.) 1992 11 p Presenting at the 95th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract DE-AC09-89SR-18035)
(DE93-013578; WSRC-MS-92-485; CONF-930438-19) Avail: CASI HC A03/MF A01

The chemical durability of 30 glasses from the Na2O * B2O3 * SiO2 * Al2O3* Fe2O3 * CaO system was examined. Two standard leach tests, MCC-1P and PCT, were performed in unbuffered, deionized water. PCT tests were performed for durations up to twenty-four weeks to obtain glass dissolution rate data. Short-term MCC-1P test leachate solutions are determined by the glass composition. Long-term glass dissolution rates, however, are dependent on glass structure in addition to glass composition. The applicability of the free energy of hydration and other dissolution and durability models to this system is discussed. DOE

PORE-SIZE-DISTRIBUTION OF CATIONIC POLYACRYLAMIDE HYDROGELS
M. Kremer and J. M. Prausnitz Jun. 1992 80 p
(Contract DE-AC03-76SF-00098)
(DE93-015218; LBL-32845) Avail: CASI HC A05/MF A01

The pore size distribution of a AAm/MAPTAC (acrylamide copolymerized with (3-methacrylamidopropyl) trimethylammonium chloride) hydrogel was investigated using Kuga's mixed-solute-exclusion method, taking into account the wall effect. A Brownian-motion model is also used. Results show the feasibility of determining pore-size distribution of porous materials using the mixed-solute-exclusion method in conjunction with solution of the Fredholm equation; good agreement was obtained with experiment, even for bimodal pore structures. However, different pore size distributions were calculated for the two different probe-solutes (Dextran and poly(ethylene glycol/oxide)). Future work is outlined. DOE

WORKSHOP ON FORMATION OF SUPERMOLECULAR STRUCTURES IN COMPOSITE FLUID: PHASE RULE AND DYNAMICS
Fumihiko Tanaka, ed., Takao Ohta, ed., and Hironobu Ikeda, ed. Oct. 1992 85 p Workshop held in Tsukuba, Japan, 2-3 Jul. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-782887; KEK-PROC-92-10; CONF-9207190) Avail: CASI HC A05/MF A01

This is the report of the workshop held at the National Laboratory for High Energy Physics on 2-3 Jul. 1992. This workshop was planned as a part of the research project on the utilization of booster neutrons in this Laboratory, and is one of the attempts to apply the technique of neutron scattering with wide visual field. Composite liquid means the solution that has the capability of forming the structure in 10-1000 nm and contains polymers, liquid crystals, micelles, or films inside. The hierarchy of the concept of supermolecules, the flexibility of the form of particles, multiple composition mixture system, and so on are the subjects in this field. In the workshop of this time, the themes were limited to three phenomena, that is, the formation of networks, microscopic phase separation and mesophase, and solvation and the formation of micelles. The measurement of neutron scattering by label method offers a powerful means hereafter for elucidating the structure and the dynamics of supermolecular liquid. DOE

MODELING SURFACE AREA TO VOLUME EFFECTS ON BOROSILICATE GLASS DISSOLUTION
W. L. Bourcier, W. L. Ebert (Argonne National Lab., IL.), and X. Feng (Argonne National Lab., IL.) Nov. 1992 8 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contracts W-7405-eng-48; W-31-109-eng-38)
(DE93-011891; UCRL-JC-112832; CONF-921101-111) Avail: CASI HC A02/MF A01

We simulated the reaction of SRL-131 glass with equilibrated J-13 water in order to investigate the effects of surface area to volume ratio (SA/V) on glass dissolution. We show that glass-fluid ion exchange causes solution pH to rise to progressively higher values as SA/V increases.

Because the ion exchange is rapid relative to the duration of the glass dissolution experiment, the pH effect does not scale with (SA/V)*time. Experiments compared at the same (SA/V)*time value have different pHs, with higher pHs at higher SA/V ratios. Both experimental data and our simulation results show similar trends of increasing reaction rate as a function of SA/V ratio when scaled to (SA/V)*time. Glasses which react in systems of differing SA/V ratio follow different reaction paths and high SA/V ratios cannot be used to generate data which accurately scales to long time periods unless the ion exchange effect is taken into account. We suggest some simple test designs which enable more reliable high. DOE

NONLINEAR WAVE PREDICTIONS IN CERAMICS
D. A. Mandell 1993 6 p Presented at the International Union of Theoretical and Applied Mechanics Symposium, Victoria, Canada, 15-20 Aug. 1993
(Contract W-7405-eng-36)
(DE93-016516; LA-UR-93-2437; CONF-9308130-1) Avail: CASI HC A02/MF A01

Accurate numerical prediction of nonlinear waves in metals and ceramics is important in the design of many products including aerospace structures, automobile engines, and other devices. The material strength and fracture of ceramics must be predicted in order to achieve optimum designs. As part of a project to develop a reliable, robust, design computer program, a number of material strength and fracture models have been implemented into the MESA-2D hydrocode and the predictions from the code have been compared to data. MESA-2D is an explicit, finite-difference Eulerian code with hydrodynamics, high explosives, material strength, fracture, and a number of equation of state models. The interface velocity as a function of time between an alumina target and a lithium fluorids window, impacted by an alumina disk at velocities between 544 m/s and 2329 m/s, was predicted by using the Steinberg ceramic material strength model and a maximum tensile fracture model. These one-dimensional flyer plate experiments were conducted at Sandia National Laboratories using Coors AD 995 alumina. DOE

PORTABLE ACOUSTIC WAVE SENSOR SYSTEMS FOR REAL-TIME MONITORING OF VOLATILE ORGANIC COMPOUNDS
R. W. Cernosek, G. C. Frye, and D. W. Gilbert 1993 8 p Presented at the Conference on Physics Computing, Albuquerque, NM, 31 May - 4 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-013753; SAND-93-0100C; CONF-930557-1) Avail: CASI HC A02/MF A01

Portable acoustic wave sensor (PAWS) systems are being developed for real-time, on-line and in situ monitoring of volatile organic compounds (VOCs). These systems are built around surface acoustic wave (SAW) devices coated with viscoelastic polymers. Two independent responses of the SAW sensor, wave velocity and attenuation, are measured to provide information about the chemical species sorbed by the coating. Sensing is rapid and reversible, and coatings can be optimized for particular chemical selectivity and sensitivity. The complete PAWS system consists of two SAW devices (a sensor and a reference), RF oscillator electronics to drive the devices, digital interface/communications electronics, gas handling hardware to sample the environment, and a notebook computer to control the hardware and display responses in real-time. These systems have been demonstrated for on-line monitoring of exhaust stack vapors in environmentally conscious manufacturing (ECM) applications, for real-time documentation of off-gas contaminants from vacuum extraction processes at DOE remediation sites, and for down-hole sensing of volatile organics in vadose zone (above the groundwater level) monitoring wells. HOW TO READ A PHASE EQUILIBRIUM DIAGRAM FOR HIGH-TEMPERATURE CERAMICS MATERIAL AS MAIN OBJECT
A. Yamaguchi 30 Aug. 1992 132 p In JAPANESE
(DE93-512333; ETDE/JP-mf-93512333) Avail: CASI HC A07/MF A02

A book on how to read a phase equilibrium diagram of high-temperature ceramic material is discussed. The book comprises three sections: fundamentals, applications, and conclusions and exercise. The fundamentals section details phase rules, equilibrium condition in binary and tertiary phase components and O-N system phase, and existence phases of molten compounds (coincidence and decomposition). The applications section describes how to read equilibrium diagrams for six phases including CaO-Al2O3-SiO2 system phases, and ten items including Al2O3-SiO2 system refractories and alkalis as well as sintering auxiliaries. The conclusions and exercise include seven precautionary items important for reading phase diagrams, the relation between Alkemade lines and boundary lines, identification of coincidence and decomposition in molten compounds, and how to distinguish characteristic curves and points. The 20 system phase diagrams in Phase Diagrams for Ceramists, published by American Ceramics Society Institutes, are used for the exercise. DOE

STRUCTURAL CHANGE OF GRAPHITE DURING ELECTRON IRRADIATION
J. Koike and D. F. Pedraza 1992 6 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015961; CONF-921101-134) Avail: CASI HC A02/MF A01

Highly oriented pyrolytic graphite was irradiated at room temperature with 300-keV electrons. High resolution transmission electron microscopy and electron energy loss spectroscopy were employed to study the structure of electron-irradiated graphite. Results consistently indicated absence of long-range order periodicity in the basal plane, and loose retention of the c-axis periodicity. Structure was modeled based on a mixture of sixfold and non-sixfold atom rings. Formation of non-sixfold atom rings was related to the observed buckling and discontinuity of the original graphite basal plane. DOE

(Grant NAG1-1067)
(NASA-CR-194521; NAS 1.26:194521) Avail: CASI HC A03/MF A01

During the past three months, significant progress has been made on the preparation of carbon fiber composites using advanced polymer resins. The results are set forth in recent reports and publications, and will be presented at forthcoming national and international meetings. Current and ongoing research activities reported herein include: textile composites from powder-coated towpreg; role of surface coating in braiding; prepregger hot sled operation; ribbonizing powder-impregenated towpreg; textile composites from powder-coated towpreg; role of bulk factor powder curtain prepreg process advanced tow placement (ATP) open-section part warpage control. During the coming months research will be directed toward further development of the new powder curtain prepregging method and on ways to customize dry powder towpreg for textile and robotic applications in aircraft part fabrication. Studies of multi-tow powder prepregging and ribbon preparation will be conducted in conjunction with continued development of prepregging technology and the various aspects of composite part fabrication using customized towpreg. Also, during the period ahead work will continue on the analysis of the performance of the new solution prepregger. Author (revised)

PROCESSING AND TESTING OF HIGH TOUGHNESS SILICON NITRIDE CERAMICS Final Report
Veena Tikare, William A. Sanders (Analex Corp., Brook Park, OH.), and Sung R. Choi (Cleveland State Univ., OH.) Sep. 1993 11 p Proposed for presentation at the Pacific Rim Meeting of the American Ceramic Society, Honolulu, HI, 7-10 Nov. 1993; sponsored by the American Ceramic Society
(Contract NAS3-133; RTOP 505-63-5A)
(NASA-CR-191190; E-8120; NAS 1.26:191190) Avail: CASI HC A03/MF A01

High toughness silicon nitride ceramics were processed with the addition of small quantities of beta-Si3N4 whiskers in a commercially available alpha-Si3N4 powder. These whiskers grew preferentially during sintering resulting in large, elongated beta-grains, which acted to toughen the matrix

by crack deflection and grain pullout. The fracture toughness of these samples seeded with beta-Si3N4 whiskers ranged from 8.7 to 9.5 MPa m(exp 0.5) depending on the sintering additives. Author (revised)

ION ASSISTED SPUTTER DEPOSITION OF Mo-Si MULTILAYERS
S. P. Vernon (Vernon Applied Physics, Torrance, CA.), D. G. Stearns, and R. S. Rosen Nov. 1992 20 p Presented at the Soft X Ray Projection Lithography Topical Meeting, Monterey, CA, 6-8 Apr. 1992
(Contract W-7405-eng-48)
(DE93-013830; UCRL-JC-109359-Rev-1; CONF-9204120-9-Rev-1) Avail: CASI HC A03/MF A01

X-ray multilayer (ML) structures fabricated utilizing magnetron sputter deposition exhibit a degradation instructural quality with increased deposition pressure. The observed change in morphology is attributed to a reduced mobility of surface adatoms which inhibits the formation of smooth, continuous layers. The application of a negative substrate bias produces ion bombardment of the growing film surface by sputtering gas ions extracted from the plasma and allows direct control of the energy density supplied to the film surface during thin film growth. The technique supplements the energy lost to thermalization in high pressure deposition and permits the fabrication of high quality ML structures at elevated processing pressures. A three fold improvement in the soft x-ray normal incidence reflectance (NIR) at 130 (Angstrom) results for substrate bias voltages of order (approximately) -150V for Mo-Si MLs deposited at 10 mTorr Ar. Equipment manufacturers are challenged to replace CFC-based refrigerants and their lubricants with environmentally acceptable alternatives. Information on the compatibility of motor materials with these alternative refrigerants and lubricants is a basic requirement for reliable performance. This report presents compatibility data for 24 commercially used motor materials exposed to 17 refrigerant/lubricant combinations. This compatibility data will enable the phase out of CFC's to continue at its current fast pace and insure the continued reliable performance of refrigerant-based equipment. DOE

THERMAL HISTORY EFFECTS ON ELECTRICAL RELAXATION AND CONDUCTIVITY FOR POTASSIUM SILICATE GLASS WITH LOW ALKALI CONCENTRATIONS
Paul W. Angel, Raiford E. Hann, and Alfred R. Cooper (Case Western Reserve Univ., Cleveland, OH.) Aug. 1993 21 p
(RTOP 505-62-70)
(NASA-TM-106324; E-8077; NAS 1.15:106324) Avail: CASI HC A03/MF A01

Electrical response measurements from 10 Hz to 100 kHz between 120 and 540 C were made on potassium-silicate glasses with alkali oxide contents of 2, 3, 5 and 10 mol percent. Low alkali content glasses were chosen in order to try to reduce the Coulombic interactions between alkali ions to the point that frozen structural effects from the glass could be observed. Conductivity and electrical relaxation responses for both annealed and quenched glasses of the same composition were compared. Lower DC conductivity (sigma(sub DC)) activation energies were measured for the quenched compared to the annealed glasses. The two glasses with the lowest alkali contents exhibited a non-Arrhenius concave up curvature in the log(sigma(sub DC)) against 1/T plots, which decreased upon quenching. A sharp decrease in sigma(sub DC) was observed for glasses containing K2O concentrations of 5 mol percent or less. The log modulus loss peak (M") maximum frequency plots against 1/T all showed Arrhenius behavior for both annealed and quenched samples. The activation energies for these plots closely agreed with the sigma(sub DC) activation energies. A sharp increase in activation energy was observed for both series as the potassium oxide concentration decreased. Changes in the electrical response are attributed to structural effects due to different alkali concentrations. Differences between the annealed and quenched response are linked to a change in the distribution of activation energies (DAE). Author (revised)

EQUATION OF STATE FOR DETONATION PRODUCTS
W. C. Davis 1993 19 p Presented at the 10th Detonation Symposium, Boston, MA, 12-16 Jul. 1993
(Contract W-7405-eng-36)
(DE93-012671; LA-UR-93-1421; CONF-930713-8) Avail: CASI HC A03/MF A01

An equation of state for detonation products, with the usual form p = p(v,E), is proposed. It allows independent calibration of the adiabatic gamma and the Grueneisen gamma, and it gives them forms in agreement with recent theoretical studies. The equation of state is given by p = E/v(k - 1 + F(v)(1 + b(1 - E/E(exp s)(v))) where F(v) drops from a finite value at small v to zero at large v, b is a constant, and E(exp s)(v) is the specific internal energy on the principal isentrope. Its relationship to the polytropic gas equation of state p = (E/v)(gamma - 1) is easily seen, and it reduces to this form at large volume. DOE

FLAMESPREADING IN GRANULAR SOLID PROPELLANT: DESIGN OF AN EXPERIMENT Final Report, Jan. 1991 - Oct. 1992
Douglas E. Kooker, Lang-Mann Chang, and Stephen L. Howard Jun. 1993 38 p
(AD-A266009; Rept-1L161102AH43) Avail: CASI HC A03/MF A01

When flamespreading in a gun system is rapid and reproducible, there is little incentive to improve our fundamental understanding of the ignition and flamespreading process. However, low-vulnerability (LOVA) propellants which are deliberately difficult to ignite can sometimes lead to anomalous ignition and flamespreading behavior. The present investigation is an attempt to study the fundamental behavior in a packed bed of granular gun propellant with a laboratory simulator. The apparatus consists of a hollow cylindrical pipe divided into two chambers. A small quantity of ball powder is burned in the igniter chamber sealed by a diaphragm and multiple-nozzle plate from the flow chamber which contains the sample granular solid propellant. Once the diaphragm bursts, combustion gases initially confined in the igniter chamber are driven through the nozzle plate forming a hot-gas planar wave which then propagates through the flow chamber. Behavior of this apparatus is discussed along with experimental pressure time-histories when the chamber is empty and filled with inert granular propellant. Results from a theoretical model help interpret some of the behavior. DTIC

CONVERSION OF LIGHT HYDROCARBON GASES TO METAL CARBIDES FOR PRODUCTION OF LIQUID FUELS AND CHEMICALS
A. F. Diaz, A. J. Modestino, J. B. Howard, and W. A. Peters Apr. 1993 6 p
(Contract DE-AC22-92PC-92111)
(DE93-014962; DOE/PC-92111/T2; FE-MIT-92111-2) Avail: CASI HC A02/MF A01

Work on this project will be performed according to two tasks. Task 1 is entitled 'Industrial Chemistry and Applied Kinetics of Light Hydrocarbon Gas Conversion to Metal Carbides H2 and CO.' We are building a laboratory-scale electric arc discharge reactor, in which to assess the technical feasibility of producing Mg2C3, H2, and CO from methane and MgO. We will also do experimental runs with CaO as well as mixtures of CaO and MgO and measure conversions of methane, CaO and/or MgO, and yields of Mg2C3, and/or CaC2, H2, and CO to identify the operating conditions of interest for implementing these reactions on a commercial scale. Reaction conditions and parameters will be chosen based on the

previous work at MIT with CaO and CH and on results of thermodynamic and thermochemical kinetics calculations. Task 2 is entitled 'Mechanistic Foundations for Converting Light Hydrocarbon Gases to Metal Carbides, H2, and CO.' We will evaluate the technical feasibility of carrying out methane reactions with CaO and MgO by thermal (e.g. 1500-2000 C) rather than under plasma conditions by performing experiments with the use of electrical screen heaters, heated tubular reactors, or other suitable apparatus. Extents and global rates of methane conversion, and yields as well as global production rates of CaC2, Mg2C3, H2, and CO will be measured upon subjecting mixtures of methane and CaO and/or MgO to high temperatures and controlled residence times. We will conduct hypothesis-testing of possible mechanistic pathways with selected experiments and perform reaction modeling to better understand the underlying chemical and physical processes that could influence process scale-up possibilities. SYNTHESIS AND CHARACTERIZATION OF 1,4-DINITROGLYCOLURIL (DINGU)
J. A. Sanchez, M. M. Stinecipher, and L. A. Stretz Jun. 1993 11 p
(Contract W-7405-eng-36)
(DE93-014111; LA-12455-MS) Avail: CASI HC A03/MF A01 (US Sales Only)

The synthesis and properties of 1,4-dinitroglycoluril (DINGU) have been studied. Isomers formed during the DINGU synthesis reaction were identified. The synthesis reaction was scaled up and reaction conditions optimized to produce the maximum yield of DINGU. This study evaluated DINGU as an energy contributing material in cast and plastic-bonded explosive formulations. Plastic coating of DINGU into a plastic-bonded explosive using several binders was also investigated. Testing indicated that DINGU has lower than expected explosive performance both as a pure material and when formulated in a plastic-bonded explosive. DOE

DESTRUCTION OF WASTE ENERGETIC MATERIALS USING BASE HYDROLYSIS
T. M. Benziger, G. A. Buntain, J. A. Sanchez, and T. Spontarelli 1993 10 p Presented at the 12th Annual International Symposium on Thermal Treatment Technologies-Incineration Conference, Knoxville, TN, 3-7 May 1993
(Contract W-7405-eng-48)
(DE93-012738; LA-UR-93-1527; CONF-930572-3) Avail: CASI HC A02/MF A01

In dismantling weapons for stockpile reduction, environmentally acceptable degradation of the associated high explosive (HE) waste to non-energetic forms is a critical objective. Base hydrolysis appears to be a simple, inexpensive method for converting propellants, explosives, and pyrotechnics (PEP's) into non-energetic materials that can be released directly or, if necessary, treated further. We have demonstrated that many PEP's can be hydrolyzed with aqueous sodium hydroxide or ammonia at temperatures ranging from 60 to 150 C. Hydrolysis experiments have been performed on pure compounds as well as DOE and DoD formulations, such as plastic-bonded explosive (PBX) 9404, tritonal, and rocket motor propellant. Small particle size of the energetic material is desirable, but not necessary. We have decomposed molding powder, pressed charges up to two pounds in weight, and partially exposed, metal-encased pieces. The products formed are dependent on the starting material composition, but usually consist of organic and inorganic salts, e.g., sodium formate, acetate, nitrite, and nitrate. The major gaseous product from the base hydrolysis of PEP's is nitrous oxide. The time required for complete destruction varies with the material being hydrolyzed and is dependent on solubility and mass transfer. Hydrolysis rates can be increased by particle size reduction, efficient stirring, and addition of organic solvent to the alkaline solution. Rate enhancement by ultrasonic agitation is a possibility that we have just begun to study. DOE

COMBUSTION-INDUCED CRACK/DEBOND PROPAGATION IN SOLID PROPELLANTS Ph.D. Thesis
Seng-Rung Wu 1992 154 p
Avail: Univ. Microfilms Order No. DA9311746

In a solid-rocket motor, combustion-induced crack/debond propagation could cause chamber over-pressurization and failure of a mission. To explore this malfunction of solid-rocket motors, experimental studies and theoretical simulations were conducted. The test samples under investigation were AP/PBAN/Al and polyester-based high-elongation metalized propellants with EPDM insulators and Kevlar/epoxy cases. Crack/debond samples were installed in a windowed test chamber and rapidly pressurized in a combustion environment. The effects of chamber pressurization rate and sample's boundary condition on the development of crack/debond propagations were studied. Three distinct modes of crack propagation (stationary, propagation, and bifurcated cracks) were observed for AP/PBAN/Al propellants, according to various chamber pressurization rates. For polyester-based high-elongation propellants, the crack propagation included propagation, zigzag, mixed, and branched modes; different types of crack propagation modes were observed from the opposite surfaces of the recovered samples. Crack speeds related to chamber pressurization rates were obtained in a correlation form. Debond propagation in a burning metalized propellant grain with a composite case was also studied. In general, the debond took place along the bondline with no branchings. The empirical correlations relating debond propagation speeds V(sub d) to chamber pressurization rates delta(p)/delta(t) were obtained in a power-law form (V(sub d) equals A(delta(p)/delta(t))(exp n)). It was found that the exponent n depends on debond geometries; however, the preexponent A is a function of material properties and sample geometries. In the theoretical approach, the mechanisms responsible for crack initiation and bifurcation were examined. A finite-difference scheme for combustion formulation in a propagating debond cavity was coupled with a finite-element analysis for propellant structural deformation and fracture. Case expansion responsible for the debond propagation was simulated. Results for the debond model include solving combustion processes in a debond flaw; calculating pressure-driven structural deformation; and simulating combustion-induced debond propagation in a motor analog. The theoretical simulation was in good agreement with experimental observations, ensuring the applicability of this model to predict a flawed solid rocket motor.

STATUS AND FUTURE OPPORTUNITIES FOR CONVERSION OF SYNTHESIS GAS TO LIQUID ENERGY FUELS Final Report
G. Mills May 1993 187 p Prepared in cooperation with Delaware Univ., Newark, DE
(Contract DE-AC02-83CH-10093)
(DE93-010025; NREL/TP-421-5150) Avail: CASI HC A09/MF A02

The manufacture of liquid energy fuels from syngas (a mixture of H2 and CO, usually containing CO2) is of growing importance and enormous potential for the following reasons: (1) Abundant U.S. supplies of coal, gas, and biomass can be used to provide the needed syngas. (2) The liquid fuels produced, oxygenates or hydrocarbons, can help lessen environmental pollution. Indeed, oxygenates are required to a significant extent by the Clean Air Act Amendments (CAAA) of 1990. (3) Such liquid synfuels make possible high engine efficiencies because they have high octane or cetane ratings. (4) There is new, significantly improved technology for converting syngas to liquid fuels and promising opportunities for further improvements. This is the subject of this report. The purpose of this report is to provide an account and evaluative assessment of advances in the technology for producing liquid energy fuels from syngas and to suggest opportunities for future research deemed promising for practical processes. Much of the improved technology for selective synthesis of desired fuels from syngas has resulted from advances in catalytic chemistry. However, novel process engineering has been particularly important recently, utilizing known catalysts in new configurations to create new catalytic processes. This report is an update of the 1988 study Catalysts for Fuels from Syngas: New Directions for Research, which is included as Appendix A. Technology for manufacture of syngas is not part of this study. The manufacture of liquid synfuels is capital intensive. Thus, in evaluating advances in fuels technology, the focus is on the potential for improved economics, particularly on lowering plant investment costs. A second important criteria is the potential for environmental benefits. The discussion is concerned with two types of hydrocarbon fuels and three types of oxygenate fuels that can be synthesized from syngas. Seven alternative reaction pathways are involved. DOE

CLOSED-CHAMBER ANALYSIS OF M5 PROPELLANT LOT RAD-64597 Final Report, Nov. 1992 - Feb. 1993
William F. Oberle Jun. 1993 137 p
(AD-A266321; ARL-MR-83) Avail: CASI HC A07/MF A02

The Advanced Propulsion Technology Branch (APTB) of the Propulsion and Flight Division (PFD) is currently engaged in the investigation of both liquid and solid propellant electrothermal-chemical (ETC) propulsion concepts. A major goal of this technology investigation is to demonstrate that ETC propulsion offers performance advantages (increase muzzle kinetic energy) in comparison to conventional solid propellant performance. To experimentally quantify differences in performance between ETC and conventional solid propellant technologies requires optimization of the propelling charges. For solid propellant ETC (SPETC) such an optimization requires an accurate knowledge of the burning characteristics (linear burn rate) of the propellant. For the APTB experimental program, one of the baseline solid propellants will be M5, lot RAD-64597. DTIC

A STUDY OF THE ROLE OF HOMOGENEOUS PROCESS IN HETEROGENEOUS HIGH EXPLOSIVES
P. K. Tang 1993 8 p Presented at the 10th Detonation Symposium, Boston, MA, 12-16 Jul. 1993
(Contract W-7405-eng-36)
(DE93-012733; LA-UR-93-1557; CONF-930713-10) Avail: CASI HC A02/MF A01

In a new hydrodynamic formulation of shock-induced chemical reaction, we can show formally that the presence of certain homogenous reaction characteristics is becoming more evident as shock pressure increase even in heterogeneous high explosives. The homogeneous reaction pathway includes nonequilibrium excitation and deactivation stages prior to chemical reaction. The excitation process leads to an intermediate state at higher energy level than the equilibrium state, and as a result, the effective activation energy appears to be lower than the value based on thermal experiments. As the pressure goes up higher, the homogeneous reaction can even surpass the heterogeneous process and becomes the dominant mechanism. DOE

NUMERICAL SIMULATION OF VELOCITY-COUPLED COMBUSTION RESPONSE OF SOLID ROCKET PROPELLANTS Ph.D. Thesis
I-Shih Tseng 1992 157 p
Avail: Univ. Microfilms Order No. DA9311736

A numerical analysis has been conducted to study solid-propellant rocket motor internal flowfields under both steady and oscillatory conditions. The formulation is based on the time-dependent Navier-Stokes equations for compressible flows, with consideration of finite-rate chemical kinetics and variable properties. Turbulence closure is achieved using a modified k-Epsilon two-equation model and a two-layer model. Both models take into account the wall-injection effect arising from the surface combustion of propellants. The analysis consists of two parts: cold-flow simulation of unsteady motions in a porous chamber, and investigation of combustion of homogeneous propellants. A time-accurate finite-difference program based on the four-stage Runge-Kutta scheme, and a finite-volume program based on the dual time-stepping integration technique, were used for the cold-flow and reacting-flow simulations, respectively. The results from cold-flow simulation indicate that while the acoustic pressure field remains one-dimensional, the acoustic velocity exhibits a more complicated oscillation behavior than a plane wave. The flow-turning loss of the acoustic field is as important as the viscous loss which occurs within the acoustic boundary layer. From the reacting-flow simulation, it was found that the strong temperature gradient within the flame zones has an effect on the distribution of acoustic velocity. The interactions between acoustic waves and gas phase chemical reactions are also demonstrated by the large amplitude of temperature fluctuations when the characteristic time scales of these two mechanisms are closely matched. The metallic jet formed by the detonation of a cylindrical explosive charge with a metal-lined cavity at one end comprises the following: a single, massive high-velocity tip particle, weighing 1-5 g and travelling at 7-10 km/sec; a jet with a velocity gradient from the tip velocity at the front to 0.5-1 km/sec at the rear end; and a slug, containing most of the liner mass, travelling at 0.5-1 km/sec. The jet eventually breaks up and its penetration is proportional to its length and depends strongly on the time to breakup and the number of fragments. Existing one-dimensional mathematical models of the jet formation process are strongly dependent on the basic assumptions made about the collapse process, so that each fits only a small range of charge designs. In the present work, a 2-dimensional numerical model was developed for calculating the pressure function; it enables the simple one-dimensional jet formation model to be combined with an accurate numerical solution of the collapse process. Shell grids are used to model the liner and the charge confinement; mass points are driven by the pressure of the detonation products acting on the area between the mass points and the velocity directions are calculated from the angles between the mass points. At the collision point, a non-steady state model due to Pugh, Eichelberger and Rostoker (the PER model) is used to determine the jet and slug masses and velocities. ISA

(Contract W-7405-eng-36)
(DE93-016605; LA-UR-93-2174; CONF-930633-1) Avail: CASI HC A03/MF A01

Uranium carbide forms complete, nearly ideal solid solutions with the refractory compounds ZrC, NbC, HfC, and TaC. These compounds have very high melting points. By incorporating uranium carbide into a solid solution, a very high melting point nuclear fuel is attained. In the present study, the thermodynamics of refractory carbide fuels as it relates to vaporization or corrosion behavior is experimentally examined. The vaporization behavior of refractory carbide fuels is modeled, based on the equilibrium partial pressures of important vapor species. DOE

The purpose of the Stabilized Electromagnetic Levitator (SEL) Phase 2 project was to develop electromagnetic (EM) positioning and heating instrumentation for containerless experimentation with specific application to low-gravity operation. The three major areas of effort were to optimize the technology in a single-axis system, characterize operation with typical materials, and develop a multi-axis positioner. The major design goals were to: control heating and positioning functions independently; use high EM frequencies to enable processing of smaller, more resistive specimens; control EM stirring in molten materials for improved quiescence; provide power sufficient for melting and low gravity positioning of metals and alloys; and maintain optical access for diagnostics. Both the single-axis and three-axis instruments were shown to be feasible for low-gravity containerless experimentation. The high operating frequencies of the SEL technology make it applicable to a much larger range of materials than are conventional, lower frequency, single-axis EM positioners. Separate control of heating and positioning functions was demonstrated for the single axis device. The three-axis instrument had the ability to control fluid motions in melts and may be applied to achieve, for the first time, a high degree of quiescence in liquid specimens that are EM positioned and heated in low-gravity. GROWTH EXPERIMENT OF NARROW BAND-GAP SEMICONDUCTOR PbSnTe SINGLE CRYSTALS IN SPACE (M-1)
Tomoaki Yamada *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 3-7 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

An experiment on crystal growth of Pb(1-x)Sn(x)Te in microgravity is planned. This material is an alloy of the compound semiconductors PbTe and SnTe. It is a promising material for infrared diode lasers and detectors in the wavelength region between 6 and 30 micron. Since the electrical properties of Pb(1-x)Sn(x)Te depend greatly on the Pb/Sn ratio and crystalline defects as well as impurity concentration, homogeneous, defect-free, high-quality crystals are anticipated. Although many growth methods, such as the pulling method, the Bridgman method, the vapor growth method, etc., have been applied to the growth of Pb(1-x)Sn(x)Te, large, homogeneous, low-defect-density crystals have not yet been grown on Earth. The unsuccessful results were caused by buoyancy-driven convection in the fluids induced by the specific gravity difference between heated and cooled fluids on Earth. A crystal is grown by cooling the melt from one end of the ampoule. In crystal growth from the melt, about 30 percent of the SnTe in the melt is rejected at the solid-liquid interface during solidification. On Earth, the rejected SnTe is completely mixed with the remaining melt by convection in the melt. Therefore, SnTe concentration in the melt, and accordingly in the crystal, increases as the crystal grows. In the microgravity environment, buoyancy-driven convection is suppressed because the specific gravity difference is negligible. In that case, the rejected SnTe remains at the solid-liquid interface and its concentration increases only at the interface. If the growth rate is higher than the PbTe-SnTe interdiffusion rate, the amount of SnTe which diffuses from the interface into the melt increases as SnTe piles up at the interface, and finally it balances the amount of rejected SnTe during solidification, resulting in steady-state SnTe transportation at the interface. By using this principle, compositionally homogeneous crystals can be grown. Furthermore, low-defect-density crystals will be grown in microgravity, because convection causes crystalline defects by mising hot and cold fluids and generating temperature fluctuations in them. GROWTH OF PbSnTe SINGLE CRYSTAL BY TRAVELING-ZONE METHOD IN LOW GRAVITY (M-2)
Y. Segawa *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 9-13 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

The single-crystal lead tin telluride (PbSnTe) semiconductor is most promising as a laser radiation element and infrared detecting element in the far infrared region. However, it is very difficult to grow a large single crystal with a homogeneous composition on Earth because the elements have a very strong tendency to separate from each other in the molten phase due to differences in their specific gravities and melting points. The purpose of the experiment is to grow a single crystal of PbSnTe by a traveling zone method in microgravity, and to study the spatial fluctuation of the composition and the electrical properties of the crystal.

GROWTH OF SEMICONDUCTOR COMPOUND SINGLE CRYSTAL InSb BY FLOATING ZONE METHOD (M-3)
I. Nakatani *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 15-19 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

Floating zone methods have potential applications in growing single high-quality semi-conductor crystals. In this method, melts can be sustained without containers and, therefore, are free from contamination from the containers. The main objective of this project is to use the Image Furnace to study a large diameter, (20 mm) single crystal of InSb under microgravity conditions. The behavior of the liquid column is recorded on the VTR tapes and is compared with what is expected theoretically. The single crystal grown in space is characterized by comparing it with single crystals grown on the ground with respect to crystallographic and electronic properties. The goal of this project is to confirm the effects of the microgravity on the single crystals. Author (revised)

An aluminum-lead-bismuth alloy is a flexible alloy and is promising for easily workable embedded-type, filament-dispersed superconducting wire material. It is difficult to produce homogeneous ingots of this material because it is easily separated into elements when melted on Earth due to the large specific gravity differences. In this experiment, a homogeneous alloy will first be produced in molten state in microgravity. It will then be returned to Earth and processed into a wire or tape form. It will then be dispersed as the second phase in micro texture form into the primary phase of aluminum. Superconducting wire material with high-critical-magnetic-field characteristics will be produced. The texture of the material will be observed, and its performance will be evaluated. In addition to the above alloy, a four-element alloy will be produced from silver, a rare Earth element, barium, and copper. The alloys will be oxidized

and drawn into wire after being returned to Earth. The materials are expected to be forerunners in obtaining superconducting wire materials from oxide superconductors. Author

FORMATION OF DEOXIDIZATION PRODUCTS IN IRON INGOT BY THE ADDITION OF Al, Si, AND/OR Mn (M-5)
Akira Fukazawa *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 27-30 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

The objective of this work is to examine the morphology, composition, and distribution of deoxidation products in iron and iron-10 percent Ni alloy ingots. The deoxidation agents Si, Mn, Al, and their mixtures are selected to investigate the formation mechanism of the deoxidation products and to compare the differences of oxide formation among these agents in microgravity. After the experiment in space, the tested specimens are going to be analyzed by the use of the latest physical and/or chemical analytical equipment, and the information obtained will be a great help for the comprehension of the formation of oxide inclusion in steel for practical purposes, and also for the study of the solidification mechanism theory in the theoretical field. PREPARATION OF PARTICLE-DISPERSION ALLOYS (M-6)
Yuji Muramatsu *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 31-35 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

A particle dispersion alloy is one type of metal-ceramic composite material, and is used as heat resistance material, wear resistance material, and electrical material. This material consists of a metal matrix and dispersed particles, and for its unique structure it has both tenacity as a metal and hardness as a ceramic. Its properties improve when the particles become finer and disperse more uniformly. Most of the particle dispersion alloys are produced by the powder metallurgical process. This process is favorable for uniform dispersion of particles, but it consists of complicated techniques such as mechanical alloying and hot extrusion, and has the following drawbacks: (1) it is difficult to fabricate large-sized products; (2) the amount of particles is limited to a few percent; and (3) the process is complicated and expensive. To overcome these drawbacks, recently special attention has been paid to conventional melting process. However, under terrestrial conditions, dispersions separate immediately due to the different specific gravities of the metal matrix and the particles and thermal convection effects. The microgravity environment is, therefore, considered to be an attractive place for fabricating the dispersion alloy. This space experiment is carried out to clarify the influence of microgravity on the properties of the particle dispersion alloy and to obtain a deeper understanding of the experiment under the microgravity environment. DIFFUSION IN LIQUID STATE AND SOLIDIFICATION OF BINARY SYSTEM (M-7)
T. Dan *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 37-39 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

Diffusion is one of the most fundamental physical phenomena. It relates to the manufacturing of almost all materials. Therefore, the precise knowledge of diffusivities of relevant materials is necessary for the optimization of these processes. On the other hand, such knowledge is indispensable to understanding the diffusion mechanism and structure of liquid metal in the field of physical metallurgy. Many diffusion experiments on solid metal were undertaken and a lot of data were accumulated. But on liquid metals there are few measurements because of experimental difficulties, such as thermal convection, induced by very slight temperature gradients in the specimen. Under microgravity conditions, the movement of liquid metal due to density differences and thermal convection must be suppressed markedly. Therefore, the transportation process will be controlled only by the diffusion of constituent atoms. These conditions offer the optimum environments for the diffusion experiment. The experiments are briefly described. Diffusion couples are prepared by attaching end to end two rods of different pure metals using hot press equipment. These couples are inserted into a graphite crucible and then doubly enclosed by two silica ampoules, respectively. The specimen is inserted into a tantalum cartridge, which is welded in a vacuum using an electron-beam apparatus. These cartridges are charged in the continuous heating furnace in space and held at a given temperature for a predetermined time and then solidified. The concentration distribution of elements in these specimens will be measured along the rod axis by means of an electron probe microanalyzer. The counterdiffusivity of the liquid metal binary system is determined on the basis of the compensated concentration distribution profile for thermal contraction. Author (revised)

HIGH TEMPERATURE BEHAVIOR OF GLASS (M-8)
Naohiro Soga *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 41-44 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

The twofold purpose of this experiment is to obtain data on the occurrence of flow in a viscous glass sphere in microgravity, and to confirm data obtained on Earth for volume-temperature relationships of glass. To do this, a cubic sample of glass laced with gold particles will be heated in the IMF. The sample's properties will be measured at high temperature, and the volume of the sample varied to measure the expansion coefficient. Movement of the gold particles, if any, will determine flow within the sample. The apparatus for this experiment is schematically shown and the photographs of the image furnace with samples before and after melting, respectively. In this apparatus, shape and size of the sample are observed by video camera and recorded by video recorder. The recorded images of the sample are schematically shown. Symbols A, B, and C denote low, intermediate, and high temperatures, respectively. From these images, the volume of the sample is estimated and the temperature dependence of the volume, is obtained. If there is agreement between the data collected in this experiment and data obtained on Earth, it would tend to verify Earth-collected data. Author (revised)

GROWTH OF Si SPHERICAL CRYSTALS AND THE SURFACE OXIDATION (M-9)
Tatau Nishinaga *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 45-49 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

Nearly 90 percent of semiconductor devices are produced with Si single crystals as the starting materials. For instance, the integrated circuits (IC), which are used in almost all electronic equipments such as TV, tape recorders, audio amplifiers, etc., are made after various processings of Si single crystal wafers. In these wafers, the same controlled amounts of impurities are added and the uniformities in their distributions are extremely important. Growth under microgravity makes it possible to eliminate the buoyancy-driven convection in the melt, which is one of the main origins of convections which results in non-uniformity of the impurity. Another source of convection is known as Marangoni convection which is driven on the free surface when a temperature gradient occurs. One of the merits of microgravity experimentation is that the detailed study of this convection becomes possible. Another important advantage of microgravity is that growth of crystals without a crucible is possible. This makes it possible to study melt growth without the strain which is usually introduced on the ground. Nevertheless, we should repeat and analyze many growth experiments in space to get reliable results. However, since in the FMPT, the time for the experiment is limited, we plan to carry out two kinds of very simple and basic experiments as the first step for the semiconductor growth experiment. In the first experiment, we use single crystal Si sphere as the starting material and as shown, this sphere is heated in the furnace at a slightly higher temperature than the melting point. After the melting front moves nearly half way to its center, the temperature is decreased to stop the melting and to start the growth from the seed for which we use the unmelted solid party of the sphere. The sphere is centered by quartz protuberances inside of the quartz crucible. There exists the possibility of temperature fluctuations being introduced when the molten sphere occasionally touches the protuberances. The total time needed for the melting and the growth processes is estimated to be 30 minutes. Infrared

emission from the sphere is monitored in order to prevent the accidental loss of the central solid core. The schematical illustration of the second experient is shown. A single crystal, Si rod is used as the starting material. In the first stage, the rod is melted from one end to obtain a liquid sphere. In the second stage, the single crystal is grown by decreasing the temperature from the unmelted part of the rod which is used as the seed. The second experient somewhat resembles the Czochralski method used on the ground; however, in the space experiment, no crucible is employed and the temperature uniformity is much superior. In both experiments, phosphorous is doped to allow observation of the change in the shape of the liquid solid interface during crystal growth and the impurity striations, if any. Author (revised)

STUDY ON SOLIDIFICATION OF IMMISIBLE ALLOYS (M-10)

Akihiko Kamio *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 51-60 (For primary document see N94-13732 02-29)

Avail: CASI HC A02/MF A03

Alloying of immiscible alloys under microgravity is of interest in metallurgical processes. Several experiments investigating the alloying of immiscible alloys, such as Al-In, Al-Bi, Zn-Bi, and Zn-Pb, were done in space. Homogeneous distribution of small L2 particles in the matrix, such as an emulsion structure, was expected in the space-solidifed alloys. However, the alloys demonstrated an extremely segregated structure. To date insufficient information was obtained to explain these unexpected results. Our experiment was proposed to clarify the solidification manner of immiscible alloys and to obtain fundamental information concerning structural control of the alloys. In space, density differences between the two liquids separated in immiscible regions can be neglected, so that no sedimentation of L(sub 2) phase will take place. When the growth of the alloys is interrupted and this status is frozen by an adequate rapid cooling procedure, it will provide much information concerning decomposing homogeneous liquid and the interaction between the monotectic growth front morphology and the distribution of L(sub 2) phase. It is anticipated that the results will be useful for elucidating the monotectic solidification manner and it will be instructive to explain the segregated structures obtained in the past space experiments. STUDY ON THE MECHANISM OF LIQUID PHASE SINTERING (M-12)

S. Kohara *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 69-74 (For primary document see N94-13732 02-29)

Avail: CASI HC A02/MF A03

The objectives were to (1) obtain the data representing the growth rate of solid particles in a liquid matrix without the effect of gravity; and (2) reveal the growth behavior of solid particles during liquid phase sintering using the data obtained. Nickel and tungsten are used as the constituent materials in liquid phase sintering. The properties of the constituent metals are given. When a compact of the mixture of tungsten and nickel powders is heated and kept at 1550 C, nickel melts down but tungsten stays solid. As the density of tungsten is much greater than that of nickel, the sedimentation of tungsten particles occurs in the experiment on Earth. The difference between the experiments on Earth and in space is illustrated. The tungsten particles sink to the bottom and are brought into contact with each other. The resulting pressure at the contact point causes the accelerated dissolution of tungsten. Consequently, flat surfaces are formed at the contact sites. As a result of dissolution and reprecipitation of tungsten, the shape of particles changes to a polygon. This phenomenon is called 'flattening.' An example of flattening of tungsten particles is shown. Thus, the data obtained by the experiment on Earth may not represent the exact growth behavior of the solid particles in a liquid matrix. If the experiments were done in a microgravity environment, the data corresponding to the theoretical growth behavior of solid particles could be achieved. Derived from text

FABRICATION OF Si-As-Te TERNARY AMORPHOUS SEMICONDUCTOR IN THE MICROGRAVITY ENVIRONMENT (M-13)

Yoshihiro Hamakawa *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 75-78 (For primary document see N94-13732 02-29)

Avail: CASI HC A01/MF A03

Ternary chalcogenide Si-As-Te system is an interesting semiconductor from the aspect of both basic physics and technological applications. Since a Si-As-Te system consists of a IV-III-II hedral bonding network, it has a very large glass forming region with a wide physical constant controllability. For example, its energy gap can be controlled in a range from 0.6 eV to 2.5 eV, which corresponds to the classical semiconductor Ge (0.66 eV), Si (1.10 eV), GaAs (1.43 eV), and GaP (2.25 eV). This fact indicates that it would be a suitable system to investigate the compositional dependence of the atomic and electronic properties in the random network of solids. In spite of these significant advantages in the Si-As-Te amorphous system, a big barrier impending the wide utilization of this material is the huge difficulty encountered in the material preparation which results from large differences in the weight density, melting point, and vapor pressure of individual elements used for the alloying composition. The objective of the FMPT/M13 experiment is to fabricate homogeneous multi-component amorphous semiconductors in the microgravity environment of space, and to make a series of comparative characterizations of the amorphous structures and their basic physical constants on the materials prepared both in space and in normal terrestrial gravity. GAS-EVAPORATION IN LOW-GRAVITY FIELD (COGELATION MECHANISM OF METAL VAPORS) (M-14)

N. Wada *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 79-82 (For primary document see N94-13732 02-29)

Avail: CASI HC A01/MF A03

When metal and alloy compounds are heated and vaporized in a rare gas such as helium, argon, or xenon, the vaporized substances diffused in the rare gas are supersaturated resulting in a smoke of fine particles of the material congealing as snow or fog. The gas vaporizing method is a fine particle generation method. Though the method has a variety of applications, the material vapor flow is disturbed by gravitational convection on Earth. The inability to elucidate the fine particle generation mechanism results in an obstruction to improving the method to mass production levels. As no convection occurs in microgravity in space, the fine particle generation mechanism influenced only by diffusion can be investigated. Investigators expect that excellent particles with homogeneous diameter distribution can be obtained. Experiment data and facts will assist in improving efficiency, quality, and scale or production processes including element processes such as vaporization, diffusion, and condensation. The objective of this experiment is to obtain important information related to the mechanism of particle formation in the gas atmosphere (smoke particles) and the production of submicron powders of extremely uniform size. DROP DYNAMICS IN SPACE AND INTERFERENCE WITH ACOUSTIC FIELD (M-15)

Tatsuo Yamanaka *In* NASA. Marshall Space Flight Center, Spacelab J

Experiment Descriptions Aug. 1993 p 83-85 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

The objective of the experiment is to study contactless positioning of liquid drops, excitation of capillary waves on the surface of acoustically levitated liquid drops, and deformation of liquid drops by means of acoustic radiation pressure. Contactless positioning technologies are very important in space materials processing because the melt is processed without contacting the wall of a crucible which can easily contaminate the melt specifically for high melting temperatures and chemically reactive materials. Among the contactless positioning technologies, an acoustic technology is especially important for materials unsusceptible to electromagnetic fields such as glasses and ceramics. The shape of a levitated liquid drop in the weightless condition is determined by its surface tension and the internal and external pressure distribution. If the surface temperature is constant and there exist neither internal nor external pressure perturbations, the levitated liquid drop forms a shape of perfect sphere. If temperature gradients on the surface and internal or external pressure perturbations exist, the liquid drop forms various modes of shapes with proper vibrations. A rotating liquid drop was specifically studied not only as a classical problem of theoretical mechanics to describe the shapes of the planets of the solar system, as well as their arrangement, but it is also more a contemporary problem of modern non-linear mechanics. In the experiment, we are expecting to observe various shapes of a liquid drop such as cocoon, tri-lobed, tetropod, multi-lobed, and doughnut. Author (revised)

STUDY OF BUBBLE BEHAVIOR IN WEIGHTLESSNESS (EFFECTS OF THERMAL GRADIENT AND ACOUSTIC STATIONARY WAVE) (M-16)
H. Azuma *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 87-88 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

The aim of this experiment is to understand how bubbles behave in a thermal gradient and acoustic stationary wave under microgravity. In microgravity, bubble or bubbles in a liquid will not rise upward as they do on Earth but will rest where they are formed because there exists no gravity-induced buoyancy. We are interested in how bubbles move and in the mechanisms which support the movement. We will try two ways to make bubbles migrate. The first experiment concerns behavior of bubbles in a thermal gradient. It is well known than an effect of surface tension which is masked by gravity on the ground becomes dominant in microgravity. The surface tension on the side of the bubble at a lower temperature is stronger than at a higher temperature. The bubble migrates toward the higher temperature side due to the surface tension difference. The migration speed depends on the so-called Marangoni number, which is a function of the temperature difference, the bubble diameter, liquid viscosity, and thermal diffusivity. At present, some experimental data about migration speeds in liquids with very small Marangoni numbers were obtained in space experiments, but cases of large Marangoni number are rarely obtained. In our experiment a couple of bubbles are to be injected into a cell filled with silicon oil, and the temperature gradient is to be made gradually in the cell by a heater and a cooler. We will be able to determine migration speeds in a very wide range of Marangoni numbers, as well as study interactions between the bubbles. We will observe bubble movements affected by hydrodynamical and thermal interactions, the two kinds of interactions which occur simultaneously. These observation data will be useful for analyzing the interactions as well as understanding the behavior of particles or drops in materials processing. The second experiment concerns bubble movement in an acoustic stationary wave. It is known that a bubble in a stationary wave moves toward the node or the loop according to whether its diameter is larger or smaller than that of the main resonant radius. In our experiment fine bubbles will be observed to move according to an acoustic field formed in a cylindrical cell. The existence of bubbles varies the acoustic speed, and the interactive force between bubbles will make the bubble behavior collective and complicated. This experiment will be very useful to development of bubble removable technology as well as to the understanding of bubble behavior.

MARANGONI EFFECT INDUCED CONVECTION IN MATERIAL PROCESSING UNDER MICROGRAVITY (M-18)
S. Enya *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 95-100 (For primary document see N94-13732 02-29)
Avail: CASI HC A02/MF A03

On the ground the upper layer of the liquid in a vessel heated from below becomes hotter than the lower layer. This well-known phenomenon results from buoyancy-induced convection. Though this means that the buoyancy-induced convection is not dominant under microgravity conditions in space, another convection called Marangoni convection may possibly occur. This convection results from an intermolecular force which acts on a free surface, that is surface tension. Since it is stronger at lower temperatures, the liquid surface near the heated wall is pulled to the cooled side as shown. This surface movement causes the inner convection. Marangoni convection, however, may be negligible on the Earth, for the molecular force is generally smaller than buoyancy. Various tests on material processing were recently conducted in space and some high quality crystals free from buoyancy convection were obtained. But, at the same time, others proved to be less uniform than expected in the components' distribution. This nonuniformity seems to be mainly caused by Marangoni convection. It is, therefore, very important to know how to control the convection by studying its characteristics, but the problem is that on the ground it is impossible to carry out the experiment without gravity. That is what a space experiment aboard the space shuttle is planned as the First Material Processing Tests (FMPT) of Japan. The experiment on Marangoni flow visualization is being performed in order to investigate the characteristics of convection in uni-dimensional melt growth under microgravity conditions.

SOLIDIFICATION OF EUTECTIC SYSTEM ALLOYS IN SPACE (M-19)
Atsumi Ohno *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 101-105 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

It is well known that in the liquid state eutectic alloys are theoretically homogeneous under 1 g conditions. However, the homogeneous solidified structure of this alloy is not obtained because thermal convection and non-equilibrium solidification occur. The present investigators have clarified the solidification mechanisms of the eutectic system alloys under 1 g conditions by using the in situ observation method; in particular, the primary crystals of the eutectic system alloys never nucleated in the liquid, but instead did so on the mold wall, and the crystals separated from the mold wall by fluid motion caused by thermal convection. They also found that the equiaxed eutectic grains (eutectic cells) are formed on the primary crystals. In this case, the leading phase of the eutectic must agree with the phase of the primary crystals. In space, no thermal convection occurs so that primary crystals should not move from the mold wall and should not appear inside the solidified structure. Therefore no equiaxed eutectic grains will be formed under microgravity conditions. Past space experiments concerning eutectic alloys were classified into two types of experiments: one with respect to the solidification mechanisms of the eutectic alloys and the other to the unidirectional solidification of this alloy. The former type of experiment has the problem that the solidified structures between microgravity and 1 g conditions show little difference. This is why the flight

samples were prepared by the ordinary cast techniques on Earth. Therefore it is impossible to ascertain whether or not the nucleation and growth of primary crystals in the melt occur and if primary crystals influence the formation of the equiaxed eutectic grains. In this experiment, hypo- and hyper-eutectic aluminum copper alloys which are near eutectic point are used. The chemical compositions of the samples are Al-32.4mass%Cu (Hypo-eutectic) and Al-33.5mass%Cu (hyper-eutectic). Long rods for the samples are cast by the Ohno Continuous Casting Process and they show the unidirectionally solidified structure. Each flight and ground sample was made of these same rods. The dimensions of all samples are 4.5 mm in diameter and 23.5 mm in length. Each sample is put in a graphite capsule and then vacuum sealed in a double silica ampoule. Then the ampoule is put in the tantalum cartridge and sealed by electron beam welding. For onbard experiments, a Continuous Heating Furnance (CHF) will be used for melting and solidifying samples under microgravity conditions. Six flight samples will be used. Four samples are hypo-eutectic and two are hyper-eutectic alloys. The surface of the two hypo-eutectic alloy samples are covered with aluminum oxide film to prevent Marangoni convection expected under microgravity conditions. Each sample will be heated to 700 C and held at that temperature for 5 min. After that the samples will be allowed to cool to 500 C in the furnace and they will be taken out of the furnace for He gas cooling. The heating and cooling diagrams for the flight experiments are shown. After collecting the flight samples, the solidified structures of the samples will be examined and the mechanisms of eutectic solidification under microgravity conditions will be determined. It is likely that successful flight experiment results will lead to production of high quality eutectic alloys and eutectic composite materials in space.

GROWTH OF SAMARSKITE CRYSTAL UNDER MICROGRAVITY CONDITIONS (M-20)

S. Takekawa *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 107-111 (For primary document see N94-13732 02-29)

Avail: CASI HC A01/MF A03

The purpose of the experiment was to grow single crystals of samarskite under microgravity conditions by the traveling solvent float zone (TSFZ) method, and to study the phase relations in the samarskite-related systems involving liquid phases by the slow cooling float zone (SCFZ) method. Samarskite is one of the minerals in a metamict state and is composed of Ca, Fe, Y, U, Th, Nb, Ta, O, etc. Alpha-particles radiating from uranium and/or thorium in the samarskite itself has destroyed its original structure without damaging its chemical composition and its external form. Consequently its structure was converted into a vitreous structure.

GROWTH EXPERIMENT OF ORGANIC METAL CRYSTAL IN LOW GRAVITY (M-21)

Hiroyuki Anzai *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 113-116 (For primary document see N94-13732 02-29)

Avail: CASI HC A01/MF A03

The purpose of this experiment is to grow large, high-quality single crystals of the organic metal (TMTTF-TCNQ) by the diffusion method without thermal fluctuation due to convection and gravitational sedimentation, and to evaluate the difference in properties between such crystals grown in low gravity and the ones obtained on Earth. The expected results may fix several physical properties of TMTTF-TCNQ, lead to the discovery of new phenomena, and enable us to analyze diffusion processes in a precise way. The result will contribute to the development of research on organic metals and, generally, on crystal growth.

CRYSTAL GROWTH OF COMPOUND SEMICONDUCTORS IN A LOW-GRAVITY ENVIRONMENT (InGaAs CRYSTALS) (M-22)

Masami Tatsumi *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 117-120 (For primary document see N94-13732 02-29)

Avail: CASI HC A01/MF A03

Compound semiconductor crystals, such as gallium arsenide and indium phosphide crystals, have many interesting properties that silicon crystals lack, and they are expected to be used as materials for optic and/or electro-optic integrated devices. Generally speaking, alloy semiconductors, which consist of more than three elements, demonstrate new functions. For example, values of important parameters, such as lattice constant and emission wavelength, can be chosen independently. However, as it is easy for macroscopic and/or microscopic fluctuations of composition to occur in alloy semiconductor crystals, it is difficult to obtain crystals having homogeneous properties. Macroscopic change of composition in a crystal is caused by the segregation phenomenon. This phenomenon is due to a continuous change in the concentration of constituent elements at the solid-liquid interfacing during solidification. On Earth, attempts were made to obtain a crystal with homogeneous composition by maintaining a constant melt composition near the solid-liquid interface, through suppression of the convection flow of the melt by applying a magnetic field. However, the attempt was not completely successful. Convective flow does not occur in microgravity because the gravity in space is from four to six orders of magnitude less than that on Earth. In such a case, mass transfer in the melt is dominated by the diffusion phenomenon. So, if crystal growth is carried out at a rate that is higher than the rate of mass transfer due to this phenomenon, it is expected that crystals having a homogeneous composition will be obtained. In addition, it is also possible that microscopic composition fluctuations (striation) may disappear because microscopic fluctuations diminish in the absence of convection. We are going to grow a bulk-indium gallium arsenide (InGaAs) crystal using the gradient heating furnace (GHF) in the first material processing test (FMPT). The structure of the sample is shown where InGaAs polycrystals in a crucible are doubly sealed in two quartz tubes for safety. The GHF consists of two zones, namely, high temperature and low temperature zones, which results in a large temperature gradient at the interface. Crystal growth is performed by moving the furnace (i.e. the temperature profile) from the left to right at a definite rate. Thus, we will grow crystals both on Earth and in space under the same conditions. As previously described, it is possible to obtain good quality crystals which are homogeneous in composition both macroscopically and microscopically due to the lack of convection in space. We are planning to study the effects of convection on crystal growth from a melt by comparing and characterizing the properties of crystals grown on Earth with those grown in space.

MICROGRAVITY ACCELERATION MEASUREMENT ENVIRONMENT CHARACTERIZATION

Richard DeLombard *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 121-127 (For primary document see N94-13732 02-29)

Avail: CASI HC A02/MF A03

The Space Acceleration Measurement System (SAMS) is a general-purpose instrumentation system designed to measure the accelerations onboard the shuttle Orbiter and shuttle/Spacelab vehicles. These measurements are used to support microgravity experiments and investigations into the microgravity environment of the vehicle. Acceleration measurement can be made at locations remote from the SAMS main instrumentation unit by the use of up to three remote triaxial sensor heads. The SAMS was developed by NASA's Lewis Research Center (LeRC) in support of NASA's microgravity science programs. In the past, numerous acceleration measurement systems have flown on various space missions. These systems were tailored to measure accelerations for a narrow set of requirements and were limited in bandwidth, dynamic range, and recording capability. In addition, these systems were mission-peculiar and not easily modified for other applications or missions. The result has been an inability to accurately assess the expected microgravity environment prior to a mission for a particular experiment and/or location. The prime science objective for SAMS on the SL-J mission will be to measure the accelerations experienced by a multitude of experiments in the two racks of the Japanese First Materials Processing Test (FMPT). The FMPT consists of a variety of materials science and life science experiments contained in racks no. 7 and no. 10. The SAMS data will be made available to the FMPT principal

investigators after the mission for their analysis with the FMPT data. A secondary science objective for SAMS will be the characterization of the acceleration environment of the Spacelab module. This will include an analysis of the acceleration transfer function of the Spacelab module which will utilize the FMPT acceleration measurement along with measurements at the rack no. 9 structure. Another analytical effort to be undertaken is a general characterization of the acceleration environment of the Spacelab as an orbiting laboratory. These analysis efforts will be in conjunction with similar measurements and analyses on other SAMS Spacelab missions.

PROTEIN CRYSTAL GROWTH

Charles E. Bugg *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 129-135 (For primary document see N94-13732 02-29)

Avail: CASI HC A02/MF A03

Proteins account for 50% or more of the dry weight of most living systems and play a crucial role in virtually all biological processes. Since the specific functions of essentially all biological molecules are determined by their three-dimensional structures, it is obvious that a detailed understanding of the structural makeup of a protein is essential to any systematic research pertaining to it. At the present time, protein crystallography has no substitute, it is the only technique available for elucidating the atomic arrangements within complicated biological molecules. Most macromolecules are extremely difficult to crystallize, and many otherwise exciting and promising projects have terminated at the crystal growth stage. There is a pressing need to better understand protein crystal growth, and to develop new techniques that can be used to enhance the size and quality of protein crystals. There are several aspects of microgravity that might be exploited to enhance protein crystal growth. The major factor that might be expected to alter crystal growth processes in space is the elimination of density-driven convective flow. Another factor that can be readily controlled in the absence of gravity is the sedimentation of growing crystal in a gravitational field. Another potential advantage of microgravity for protein crystal growth is the option of doing containerless crystal growth. One can readily understand why the microgravity environment established by Earth-orbiting vehicles is perceived to offer unique opportunities for the protein crystallographer. The near term objectives of the Protein Crystal Growth in a Microgravity Environment (PCG/ME) project is to continue to improve the techniques, procedures, and hardware systems used to grow protein crystals in Earth orbit. HEALTH MONITORING OF JAPANESE PAYLOAD SPECIALIST: AUTONOMIC NERVOUS AND CARDIOVASCULAR RESPONSES UNDER REDUCED GRAVITY CONDITION (L-0) **c52**

Chiharu Sekiguchi *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 139-144 (For primary document see N94-13732 02-29)

Avail: CASI HC A02/MF A03

In addition to health monitoring of the Japanese Payload Specialists (PS) during the flight, this investigation also focuses on the changes of cardiovascular hemodynamics during flight which will be conducted under the science collaboration with the Lower Body Negative Pressure (LBNP) Experiment of NASA. For the Japanese, this is an opportunity to examine firsthand the effects of microgravity of human physiology. We are particularly interested in the adaption process and how it relates to space motion sickness and cardiovascular deconditioning. By comparing data from our own experiment to data collected by others, we hope to understand the processes involved and find ways to avoid these problems for future Japanese astronauts onboard Space Station Freedom and other Japanese space ventures. The primary objective of this experiment is to monitor the health condition of Japanese Payload Specialists to maintain a good health status during and after space flight. The second purpose is to investigate the autonomic nervous system's response to space motion sickness. To achieve this, the function of the autonomic nervous system will be monitored using non-invasive techniques. Data obtained will be employed to evaluate the role of autonomic nervous system in space motion sickness and to predict susceptibility to space motion sickness. The third objective is evaluation of the adaption process of the cardiovascular system to microgravity. By observation of the hemodynamics using an echocardiogram we will gain insight on cardiovasc[illegible]tioning. The last objective is to create a data base for use in the health care of Japanese astronauts by obtaining control data in experiment L-O in the SL-J mission.

ENDOCRINE AND METABOLIC CHANGES IN PAYLOAD SPECIALIST (L-1) **c52**

Nobuo Matsui *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 145-149 (For primary document see N94-13732 02-29)

Avail: CASI HC A01/MF A03

The endocrine system plays an important role in the adaptation to unusual environments by secreting hormones to control metabolism. Since human beings have long evolved on the surface of the Earth under a gravity environment, the weightless environment must be quite unusual for them. The purpose of this experiment is to study the mechanisms of human adaptation to a weightless environment from endocrine and metabolic changes. Our study plan is focused on four major physiological changes which were reported during past space flights or which may be expected to occur under that condition: (1) hormone and metabolic changes associated with fluid shift; (2) bone demineralization and muscle atrophy; (3) altered circadian rhythm; and (4) stress reaction during space flight.

NEUROPHYSIOLOGICAL STUDY ON VISUO-VESTIBULAR CONTROL OF POSTURE AND MOVEMENT IN FISH DURING ADAPTATION TO WEIGHTLESSNESS **c52**

Shigeo Mori *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 151-153 (For primary document see N94-13732 02-29)

Avail: CASI HC A01/MF A03

We can stand upright and walk smoothly without paying any particular attention to it. This is because we have established in ourselves an integration center that controls our body subconsciously in response to input from eyes, muscles, joints, foot soles, and also from the gravity sensor in the inner ear (the otolith organ). It has been shown that the cerebellum plays an important role for the establishment of the integration center and that the control pattern is comparable to that of a highly sophisticated computer system. The programming for the control, however, may well be acquired for the 1-g ground condition and does not cover the 0-g in space. Although each of the above organs function as it does on the ground, the signal pattern sent to the center must be different under 0-g and, in addition, complementary signals from the otolith organ are missing, leading to confusion in the integration center and causing a variety of symptoms similar to those of car-sickness or sea-sickness. After exposure to microgravity an immediate process of re-programming will begin and be completed in 2-4 days. There is strong supporting evidence for this sensory conflict theory as an explanation for space motion sickness (SMS) episodes. Fish were selected as test organisms for this investigation because they swim around freely in three dimensions and have well-developed organs for vision and gravity detection. They also have an innate nature to orient their back toward a light source. Actually, on the ground, the fish tilts its vertical axis toward the light when illuminated laterally, and the tilt angle is a function of the intensity of light and the magnitude of gravity, while its posture is completely light-dependent in the low-gravity environment produced by aircraft parabolic flight or when the otolith organs are removed. This implies that fish posture is entirely under visual and otolithic control. In this case, the cerebellum will also contribute to the control. In the space shuttle experiment, two fish (one with otolith-removed and the other with intact otoliths) are onboard for 7 days. The arrangement of the experiment is shown. Lamps illuminate each fish alternately from different directions at a duration of 20 seconds for 10 minutes totally, twice a day. The video images and the brain waves from the cerebellum are analyzed later. If the sensory conflict theory is acceptable, then the confusion at the onset and the following recovery process will be manifested both in the light-dependent behavior and also in the cerebellar activity. In addition, there should be some variation in response between the two fish. Even if the results are positive in the present fish experiment, they would not be extensive enough to allow us to understand the complete mechanisms of

SMS. However, what is currently needed is a collection of evidence based on animal experiments on which to base future investigations. Countermeasures for SMS are mandatory since SMS-induced vomiting occurring within a space suit could be fatal for a crew member during extravehicular activities. We expect that countermeasures will be developed before the space station era starts, and that the results of these studies will be applied to improving human welfare. Author (revised)

SEPARATION OF BIOGENIC MATERIALS BY ELECTROPHORESIS UNDER ZERO GRAVITY (L-3) **c51**
Masao Kuroda *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 155-160 (For primary document see N94-13732 02-29)
Avail: CASI HC A02/MF A03

Electrophoresis separates electrically charged materials by imposing a voltage between electrodes. Though free-flow electrophoresis is used without carriers such as colloids to separate and purify biogenic materials including biogenic cells and proteins in blood, its resolving power and separation efficiency is very low on Earth due to sedimentation, flotation, and thermal convection caused by the specific gravity differences between separated materials and buffer solutions. The objective of this experiment is to make a comparative study of various electrophoresis conditions on the ground and in zero-gravity in order to ultimately develop a method for separating various important 'vial' components which are difficult to separate on the ground. COMPARATIVE MEASUREMENT OF VISUAL STABILITY IN EARTH AND COSMIC SPACE (L-4) **c52**
Kazugo Koga *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 161-163 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

The frequency and the intensity of space motion sickness was reviewed and investigated. Unusual induced-gravity situations, such as rotation, linear acceleration, parallel swinging etc. were investigated as well. Visually-induced motion sensation or distorted perception were evaluated with respect to visual stability by many investigators. These studies are all concerned with the effect of gravity and the induction of motion sickness through human visual perception. Direct investigation under the microgravity situation, such as parabolic flight, Skylab, and Spacelab, was carried out. These studies focused on how human visual stability is established through various sensory afferents in specific gravity conditions. Results from these investigations indicate that sensory mismatch probably plays an important role in space motion sickness. The interaction of visual, vestibular, and somatosensory perception is smoothly coordinated under normal gravitational conditions on the Earth in our daily life. When the cooperation is destroyed or a mismatch occurs among them, motion sickness may develop not only on the Earth but also in microgravity. The latter case may be the cause of space motion sickness or space adaption syndrome. How human beings obtain visual stability even with posture changes on the ground was investigated. Visual stability can be categorized as static or dynamic. Static visual stability is concerned with orientation and dynamic stability is concerned with object motion perception. The perception of visual stability is modified by many other sensations, such as somatosensory, vestibular, and muscle tension. We will mainly focus on modifications by vestibular inputs to visual perception produced by eye movements in microgravity. The Vestibular-Oscular Reflex (VOR) is a well-known characteristic which results from the relationship between eye mobility and vestibular afferent inputs. Eye movements also modify dynamic visual perception, such as perceived object motion velocity. The VOR is constantly simulated under 1-g conditions on Earth. In fact, human beings have been habituated and 'programmed' for orientation (visual stability) in their everyday, 1-g environment. When humans are exposed to a different gravity situation, this programmed behavior must change; that is, it is reprogrammed. This is called habituation or familiarization. We hope to examine how object motion perception is perturbed and subsequently adapted in the microgravity environment. This experiment is focused on the cooperation of visual, vestibular, and somatosensory perception coordination and how it is changed or reduced in space compared to 1-g environment. We will obtain information on the coordination between eye movement and neck muscle activity by using EOG and EMG. We will also collect data from Payload Specialists using a self-diagnostic questionnaire concerned with perceptual abnormality. When each sensory input function and its integration in the higher nervous system are well-characterized, then more effective techniques to control SAS may be developed. Author (revised)

CRYSTAL GROWTH OF ENZYMES IN LOW GRAVITY (L-5)
Yuhei Morita *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 165-170 (For primary document see N94-13732 02-29)
Avail: CASI HC A02/MF A03

Recent developments in protein engineering have expanded the possibilities of studies of enzymes and other proteins. Now such studies are not limited to the elucidation of the relationship between the structure and function of the protein. They also aim at the production of proteins with new and practical functions, based on results obtained during investigation of structure and function. For continuing research in this field, investigation of the tertiary structure of proteins is important. X-ray diffraction of single crystals of protein is usually used for this purpose. The main difficulty is the preparation of the crystals. The theme of the research is to prepare such crystals at very low gravity, with the main purpose being to obtain large single crystals of proteins suitable for x-ray diffraction studies. STUDIES ON THE EFFECTS OF MICROGRAVITY ON THE ULTRASTRUCTURE AND FUNCTIONS OF CULTURED MAMMALIAN CELLS (L-6) **c51**
Atsushige Sato *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 171-172 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

The human body consists of 10(exp 13) cells. Understanding the mechanisms by which the cells sense and respond to microgravity is very important as the basis for space biology. The cells were originally isolated aseptically from mammalian bodies and cultured in vitro. A set of cell culture vessels was developed to be applied to three kinds of space flight experiments. Experiment 1 is to practice the cell culture technique in a space laboratory and obtain favorable growth of the cells. Aseptic handling in tryspin treatment and medium renewal will be tested. The cells, following space flight, will be returned to the ground and cultured continuously to investigate the effects of space flight on the cellular characteristics. Experiment 2 is to examine the cytoskeletal structure of the cells under microgravity conditions. The cytoskeletal structure plays essential roles in the morphological construction, movements, axonal transport, and differentiation of the cells. The cells fixed during space flight will be returned and the cytoskeleton and ultrastructure observed using electron microscopy and fluorescence microscopy. Experiment 3 is to study the cellular productivity of valuable substances. The waste medium harvested during space flight are returned and quantitated for the cellular products. The effects of microgravity on mammalian cells will be clarified from the various aspects. Author (revised)

GRAVITY, CHROMOSOMES, AND ORGANIZED DEVELOPMENT IN ASEPTICALLY CULTURED PLANT CELLS **c51**
Abraham D. Krikorian *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 173-176 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

The objectives of the PCR experiment are: to test the hypothesis that microgravity will in fact affect the pattern and developmental progression of embryogenically competent plant cells from one well-defined, critical stage to another; to determine the effects of microgravity in growth and differentiation of embryogenic carrot cells grown in cell culture; to determine whether microgravity or the space environment fosters an instability of the differentiated state; and to determine whether mitosis and chromosome behavior are adversely affected by microgravity. The methods employed will consist of the following: special embryogenically competent carrot cell cultures will be grown in cell culture chambers provided by NASDA; four

cell culture chambers will be used to grow cells in liquid medium; two dishes (plant cell culture dishes) will be used to grow cells on a semi-solid agar support; progression to later embryonic stages will be induced in space via crew intervention and by media manipulation in the case of liquid grown cell cultures; progression to later stages in case of semi-solid cultures will not need crew intervention; embryo stages will be fixed at a specific interval (day 6) in flight only in the case of liquid-grown cultures; and some living cells and somatic embryos will be returned for continued post-flight development and 'grown-out.' These will derive from the semi-solid grown cultures. Author (revised)

EFFECT OF LOW GRAVITY ON CALCIUM METABOLISM AND BONE FORMATION (L-7) **c52**
Tatsuo Suda *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 177-178 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

Recently, attention has been focused on the disorders of bone and calcium metabolism during space flight. The skeletal system has evolved on the Earth under 1-g. Space flights under low gravity appear to cause substantial changes in bone and calcium homeostasis of the animals adapted to 1-g. A space experiment for the First Materials Processing Test (FMPT) was proposed to examine the effects of low gravity on calcium metabolism and bone formation using chick embryos loaded in a space shuttle. This space experiment was proposed based on the following two experimental findings. First, it has been reported that bone density decreases significantly during prolonged space flight. The data obtained from the US Skylab and the U.S.S.R. Salyut-6 cosmonauts have also documented that the degree of bone loss is related to the duration of space flight. Second, the US-Soviet joints space experiment demonstrated that the decrease in bone density under low gravity appears to be due to the decrease in bone formation rather than the increase in bone resorption. The purpose of our space experiment is, therefore, to investigate further the mechanisms of bone growth under low gravity using fertilized chick embryos. Author (revised)

GENETIC EFFECTS OF HZE AND COSMIC RADIATION (L-9) **c51**
Mituo Ikenaga *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 181-184 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

The purpose of our experiment is to detect mutations in Drosophila possibly induced by space radiation during the SL-J mission, so that we will be able to obtain basic information about 'the genetic (mutational) risk of space radiation' which can be used to estimate human risk of cancer induction by space flight. As an example of somatic mutation, we will analyze morphological changes in hair growing on the surface of the wing of an adult fly. A piece of wing consists of about 30 thousand wing cells and in the wild type Drosophila a long single piece of hair is growing on the surface of each wing cell. When Drosophila is exposed to radiation as its early stage of development, such as embryonic stage or larval (maggot) stage, some mutations will appear in the wing hair of the adult fly with a certain low frequency, depending on the radiation dose. Among the mutations, the most frequent one is a change in the number of hairs per cell, that is, usually three or more hairs are coming out from a single wing cell. In the actual SL-J flight, we will install thousands of Drosophila larvae (maggots) into the Space Shuttle Discovery and expose them to space radiation during the 7-day mission. Immediately after the re-entry to the ground, these larvae are expected to develop (emerge) into adult flies. Then the wings will be fixed by ethylalcohol and permanent samples will be prepared. Finally, we will analyze the wing samples microscopically in order to detect mutations. Author (revised)

MANUAL CONTROL IN SPACE RESEARCH ON PERCEPTUAL-MOTOR FUNCTIONS UNDER ZERO GRAVITY CONDITIONS (L-10) **c54**
Akira Tada *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 185-187 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

Are human abilities to control vehicles and other machines the same in space as those on Earth? The L-10 Manual Control Experiment of the First Materials Processing Tests (FMPT) started from this question. Suppose a pilot has the task to align the head of a space vehicle toward a target. His actions are to look at the target, to determine the vehicle movement, and to operate the manipulator. If the activity of the nervous system were the same as on Earth, the movements, of the eye and hand would become excessive because the muscles do not have to oppose gravity. The timing and amount of movement must be arranged for appropriate actions. The sensation of motion would also be affected by the loss of gravity because the mechanism of the otolith, the major acceleration sensor, depends on gravity. The possible instability of the sensation of direction may cause mistakes in the direction of control of manipulator movement. Thus, the experimental data can be used for designing man-machine systems in space, as well as for investigation of physiological mechanisms. In this experiment, the direction of vehicle heading is expressed by a light spot on an array of light emitting diodes and the manipulator is of a finger stick type. As the light spot moves up and down, the Japanese Payload Specialist, and the subject, must move the manipulator forward and backward to keep the movement of the light spot within the neighborhood of the central point of the display. The position of the light spot is computed in such a manner that when the stick is kept at the neutral position, a motion whose acceleration is proportional to the angle of deflection is added to the movement of the light spot. The Operator Describing Function, which is an expression of human control characteristics, can be calculated from 2 minutes of raw data of the light spot position and stick deflection. The 2 minutes of operation is called a run, and 8 runs with resting periods composes a session. The on-orbit experiment will be conducted on the second, fourth, and seventh days. One session of experiment of each of these days is conducted following the L-4 experiment, which uses the same apparatus. The Payload Specialist, aided by a Mission Specialist, will take our apparatus from a rack container, set up the apparatus, attach electrodes for measurements of eye movement and muscle activity, conduct the L-4 Visual Stability Experiment, conduct one session of the manual control experiment, and then dissemble and stow the apparatus. In addition to the flight experiment, pre-flight and post-flight experiments will be conducted. The data of three sessions on orbit will reflect adaption of physiological systems to microgravity. The data of post-flight experiments, on the other hand, will reflect re-adaptation of physiological systems to the gravity condition on the ground. Control data collected with and without psychological tension will be scheduled just prior to and long before launch. Author (revised)

NASDA is now participating in a series of flight experiments on Spacelab missions. The first experiment was carried out on the first International Microgravity Laboratory Mission (IML-1) January 1992, and the second experiment will be conducted on the Spacelab-J Mission, First Materials Processing Test (FMPT). The equipment or Radiation Monitoring Container Devices (RMCD) includes passive dosimeter systems and biological specimens. The experiments using this hardware are designed by NASDA to measure and investigate the radiation levels inside spacecraft like space shuttle and to look at the basic effects of the space environment from the aspect of radiation biology. The data gathered will be analyzed to understand the details of biological effects as well as the physical nature of space radiation registered in the sensitive Solid-State Track Detectors (SSTD). A CIRCADIAN RHYTHM OF CONIDIATION IN NEUROSPORA CRASSA (L-12) **c51**
Yashuhiro Miyoshi *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 197-200 (For primary document see N94-13732 02-29)
Avail: CASI HC A01/MF A03

Two fungi growth chambers containing six growth tubes each are

used in this experiment. One chamber is for the space experiment; the other is for the simultaneous ground control experiment. The hyphae of Neurospora crassa band A mutant are inoculated at one end of each tube. Both the chambers are kept at 3 C plus or minus 1.5 C to stop hyphae growth until the Spacelab is activated. After the activation, each chamber is transferred simultaneously to the Spacelab and a phytotron in KSC and kept in continuous light at the same temperature. After about 24 hours of light exposure, each chamber is inserted into a growth chamber bag to keep it in constant darkness. The circadian rhythm of conidiation is initiated by this light to dark transition. After the dark incubation for 5 days at room temperature, both the growth chambers are kept at 3 C plus or minus 1.5 C to stop growth of the hyphae. After the space shuttle lands, both conidiation patterns are compared and analyzed. It has been known that numerous physiological phenomena show circadian rhythms. They are characterized by the fact that the oscillation can persist under constant conditions of light and temperature. Therefore, it has been accepted by most investigators that the generation mechanism of the circadian rhythm is endogeneous. However, one cannot reject the possibility that these rhythms are caused by some geophysical exogeneous factor having a 24-hour period, such as atmospheric pressure, gravity, or electromagnetic radiation. We use Neurospora crassa band A mutual which shows an obvious circadian rhythm in its spore-forming (conidiation) on the ground, and we intend to attempt the conidation of this mutant in the Spacelab where 24-hour periodicity is severely attenuated and to elucidate the effect of the geophysical exogeneous factor in the generation mechanism of the circadian rhythm. During the year before launch, female frogs will be tested every 3 months for the quantity and quality of eggs produced. Two weeks or more prior to launch, male and female frogs will be transported to the John F. Kennedy Space Center (KSC). During the few weeks before launch, groups will be periodically tested for egg quality to assure that the frogs have adapted to the KSC laboratory environment. About 27 hours before launch, four females will be placed in a damp foam-lined box, called the Adult Frog Box (AFB), through which 100 cc/min of air wil be circulated. The AFB will be lowered into the Spacelab and loaded into the Frog Environmental Unit (FEU) during the final pre-launch preparations. A sperm suspension, for use in flight to fertilize the eggs, will also be prepared and loaded during the pre-launch period. The sperm suspension, together with a kit of syringes containing Human Chorionic Gonadotropin (HCG), will be stored in a refrigerator aboard the shuttle until needed in flight. On the first day of flight, the AFB will be transferred from the FEU to the General Purpose Work Station (GPWS), which is a type of glove box specially designed to allow the crew to use chemicals and biological materials during the flight without contaminating the shuttle/Spacelab environment. Inside the GPWS the four adult frogs will be injected with the HCG hormone and returned to the FEU. Approximately 16 hours after injection, ovulation should have taken place and 15 to 20 eggs from each frog will be placed on each of two egg baskets and covered with sperm for 10 minutes. The egg baskets are inserted into acrylic egg chambers and 50 ml of 'pond water' (20 percent strength Modified Ringers solution (is added. One of the chambers from each frog will be placed on a centrifuge within the FEU and rotated to simulate normal terrestrial gravity (1 g). The remaining chambers are incubated under microgravity conditions within the FEU. Forty minutes after fertilization, the four chambers exposed to 1 g will be removed and observed within the GPWS using a dissecting microscope and camera system. On the basis of egg rotation and egg appearance, the 'best' and 'second best' frogs will be selected to contribute additional eggs. Using the two best frogs, 22 egg chambers will be loaded with eggs and fertilized. Eleven chambers wil be incubated at microgravity and eleven will be incubated on the centrifuge. At various times during the flight, chambers will be removed from the FEU and transferred to the GPWS where a formaldehyde-based fixative will be injected in order to preserve important developmental stages for in depth study following the flight. Five of the 22 chambers plus the eight fertilization test chambers will be returned to Earth with live tadpoles. The swimming behavior of these free swimming tadpoles will be examined within several hours of landing and some will be fixed for a detailed analysis of their inner ear, the otolity, the animals 'balance system.' Lychakov and Vinikov reported an increase in otolith size in tadpoles that developed (but were not fertilized) in space. Live tadpoles from the SL-J flight will be raised through metamorphsis for studies of maturation including an analysis of the effects of space flight on their ability to produce normal progency. Following the flight, the fixed embryos will be serially sectioned and stained using procedures that were developed for this experiment. The embroys fixed at the 2-4 cell stage will be examined for the distribution of cytoplasmic contents, including the various classes of yolk platelets, and the location and shape of the cleavage furrows. The gastrulae will be assessed for the normality of the complex cellular rearrangements that constitute blastopore formation and involution, i.e., the differentiation of the embryo into its specialized body parts. Using a new procedure, the gastrulae will be bleached which will enable the initial sperm entry point (SEP) to be located. The correlation between the SEP and the dorsal lip of the blastopore will be determined. Under normal terrestrial conditions it was shown that the SEP typically is located on the side of the egg opposite the future dorsal side of the embryo. The neurulae will be examined for the normality and completeness of the neural plate and archenteron expansion. The tadpole stages will be used to study the allometry and morphology of the various organ systems. Author (revised)

MAGNETIC RESONANCE IMAGING AFTER EXPOSURE TO MICROGRAVITY **c52**

Adrian LeBlanc *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 209-211 (For primary document see N94-13732 02-29)

Avail: CASI HC A01/MF A03

A number of physiological changes were demonstrated in bone, muscle, and blood from exposure of humans and animals to microgravity. Determining mechanisms and the development of effective countermeasures for long-duration space missions is an important NASA goal. Historically, NASA has had to rely on tape measures, x-ray, and metabolic balance studies with collection of excreta and blood specimens to obtain this information. The development of magnetic resonance imaging (MRI) offers the possibility of greatly extending these early studies in ways not previously possible; MRI is also non-invasive and safe; i.e., no radiation exposure. MRI provides both superb anatomical images for volume measurements of individual structures and quantification of chemical/physical changes induced in the examined tissues. This investigation will apply MRI technology to measure muscle, intervertebral disc, and bone marrow changes resulting from exposure to microgravity. Author (revised)

COUNTERMEASURE FOR REDUCING POST-FLIGHT ORTHOSTATIC INTOLERANCE: LOWER BODY NEGATIVE PRESSURE (LBNP) EXPERIMENT E140 **c52**

John B. Charles *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 213-222 (For primary document see N94-13732 02-29)

Avail: CASI HC A02/MF A03

Investigators have shown that after 1-2 weeks of bed rest ingestion of 1000 ml of a salt water solution during 4 hours of continuous exposure to 30 mm Hg of lower body negative pressure will protect plasma volume and orthostatic function for up to 24 hours. We hypothesize that a similar countermeasure will reduce the effects of fluid loss induced by headward fluid shift during space flight. The objective of this flight experiment is to evaluate the efficacy of the proposed countermeasure in reversing these effects on the cardiovascular system. Lower Body Negative Pressure (LBNP) involves exposing the legs and lower abdomen to reduced air pressure. The LBNP device is an air-tight chamber that seals the subject's waist to enclose the lower body. As used in this experiment, LBNP provides both the candidate treatment as well as the means of assessing the effectiveness of the treatment. Author (revised)

The experiments described are aimed at exploring PTH regulation of production of collagenase and protein inhibitors of collagenase (tissue inhibitors of metalloproteases, TIMP-1 and -2) by osteoblast-like osteosarcoma cells under conditions of weightlessness. The results of this work will contribute to information as to whether a microgravity environment alters the functions and responsiveness of the osteoblast. The objectives of the Bone Culture Research (BCR) experiment are: to observe the effects of microgravity on the morphology, rate of proliferation, and behavior of the osteoblastic cells, UMR 106-01; to determine whether microgravy affects the hormonal sensitivity of osteroblastic cells; and to measure the secretion of collagenase and its inhibitors into the medium under conditions of microgravity. The methods employed will consist of the following: the osteoblast-like cells, UMR-106-01, will be cultured in four NASDA cell culture chambers; two chambers will be subjected to microgravity on SL-J; two chambers will remain on the ground at KSC as ground controls but subjected to an identical set of culture conditions as on the shuttle; media will be changed four times; twice the cells will receive the hormone parathyroid hormone-related protein (PTHrP) and media collected; cells will be photographed under conditions of microgravity; and media and photographs will be analyzed upon return to determine whether functions of the cells changed. AUTOGENIC FEEDBACK TRAINING EXPERIMENT: A PREVENTATIVE METHOD FOR SPACE MOTION SICKNESS **c52**
Patricia S. Cowings *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 227-248 (For primary document see N94-13732 02-29)
Avail: CASI HC A03/MF A03

Space motion sickness is a disorder which produces symptoms similar to those of motion sickness on Earth. This syndrome has affected approximately 50 percent of all astronauts and cosmonauts exposed to microgravity in space, but it differs from what is commonly known as motion sickness in a number of critical ways. There is currently no ground-based method for predicting susceptibility to motion sickness in space. Antimotion sickness drugs have had limited success in preventing or counteracting symptoms in space, and frequently caused debilitating side effects. The objectives were: (1) to evaluate the effectiveness of Autogenic-Feedback Training as a countermeasure for space motion sickness; (2) to compare physiological data and in-flight symptom reports to ground-based motion sickness data; and (3) to predict susceptibility to space motion sickness based on pre-flight data of each treatment group crew member. IN-FLIGHT DEMONSTRATION OF THE SPACE STATION FREEDOM HEALTH MAINTENANCE FACILITY FLUID THERAPY SYSTEM (E300/E05) **c54**
Charles W. Lloyd *In* NASA. Marshall Space Flight Center, Spacelab J Experiment Descriptions Aug. 1993 p 249-257 (For primary document see N94-13732 02-29)
Avail: CASI HC A02/MF A03

The Space Station Freedom (SSF) Health Maintenance Facility (HMF) will provide medical care for crew members for up to 10 days. An integral part of the required medical care consists of providing intravenous infusion of fluids, electrolyte solutions, and nutrients to sustain an ill or injured crew member. In terrestrial health care facilities, intravenous solutions are normally stored in large quantities. However, due to the station's weight and volume constraints, an adequate supply of the required solutions cannot be carried onboard SSF. By formulating medical fluids onboard from concentrates and station water as needed, the Fluid Therapy System (FTS) eliminates weight and volume concerns regarding intravenous fluids. The first full-system demonstration of FTS is continuous microgravity will be conducted in Spacelab-Japan (SL-J). The FTS evaluation consists of two functional objectives and an in-flight demonstration of intravenous administration of fluids. The first is to make and store sterile water and IV solutions onboard the spacecraft. If intravenous fluids are to be produced in SSF, successful sterilization of water and reconstituting of IV solutions must be achieved. The second objective is to repeat the verification of the FTS infusion pump, which had been performed in Spacelab Life Sciences - 1 (SLS-1). during SLS-1, the FTS IV pump was operated in continuous microgravity for the first time. The pump functioned successfully, and valuable knowledge on its performance in continuous microgravity was obtained. Finally, the technique of starting an IF in microgravity will be demonstrated. The IV technique requires modifications in microgravity, such as use of restraints for equipment and crew members involved. Author (revised)

THE FEASIBILITY OF PRODUCING ALUMINUM-LITHIUM STRUCTURES FOR CRYOGENIC TANKAGE APPLICATIONS BY LASER BEAM WELDING
R. P. Martukanitz and K. G. Lysher Apr. 1993 74 p Prepared in cooperation with the Space and Naval Warfare Systems Command, Washington, DC
(NASA Order L-4409-D; RTOP 505-63-50-03)
(NASA-CR-191527; NAS 1.26:191527; TM-93-067) Avail: CASI HC A04/MF A01

Aluminum-lithium alloys exhibit high strength, high elastic modulus, and low density as well as excellent cryogenic mechanical properties making them ideal material candidates for cryogenic tanks. NASA has proposed the use of 'built-up' structure for panels fabricated into cryogenic tanks replacing current conventional machining. Superplastically formed stiffeners would be joined to sheet (tank skin) that had been roll formed to the radius of the tank in order to produce panels. Aluminum-lithium alloys of interest for producing the built-up structure include alloy 2095-T6 stiffeners to 2095-T8 sheet and alloy 8090-T6 stiffeners to 2090-T83 sheet. Laser welding, with comparable joint properties, offers the following advantages over conventional welding: higher production rates, minimal degradation within the heat affected zones, and full process automation. This study established process parameters for laser beam welding, mechanical property determinations, metallographic characterization, and fabrication of prototype panels. Tensile tests representing partial penetration of the skin alloys provided joint efficiencies between 65 and 77 percent, depending upon alloy and degree of penetration. Results of tension shear tests of lap welds indicated that the combination of 2095-T6 to 2090-T8 exhibited significantly higher weld shear strength at the interface in comparison to welds of 8090-T6 to 2090-T83. The increased shear strength associated with 2095 is believed to be due to the alloy's ability to precipitation strengthening (naturally age) after welding. Author (revised)

ARTI REFRIGERANT DATABASE
J. M. Cain 30 Apr. 1993 121 p
(Contract DE-FG02-91CE-23810)
(DE93-014774; DOE/CE-23810/11D) Avail: CASI HC A06/MF A02

The Refrigerant Database consolidates and facilitates access to information to assist industry in developing equipment using alternative refrigerants. The underlying purpose is to accelerate the phase out of chemical compounds of environmental concern. The database provides bibliographic citations and abstracts for publications that may be useful in the research and design of air-conditioning and refrigeration equipment. The complete documents are not included. The database identifies sources of specific information on R-32, R-123, R-124, R-125, R-134, R-134a, R-141b, R-142b, R-143a, R-152a, R-245ca, R-290 (propane), R-717 (ammonia), ethers, and others as well as azeotropic and zeotropic blends of these fluids. It addresses lubricants including alkylbenzene, polyalkylene glycol, ester, and other synthetics as well as mineral oils. It also references documents addressing compatibility of refrigerants and lubricants with metals,

plastics, elastomers, motor insulation, and other materials used in refrigerant circuits. Incomplete citations or abstracts are provided for some documents to accelerate availability of the information and will be completed or replaced in future updates. DOE

A SUPERCONDUCTING LARGE-ANGLE MAGNETIC SUSPENSION Final Report
James R. Downer, George V. Anastas, Jr., Dariusz A. Bushko, Frederick J. Flynn, James H. Goldie, Vijay Gondhalekar, Timothy J. Hawkey, Richard L. Hockney, and Richard P. Torti Dec. 1992 328 p
(Contract NAS1-18853; SBIR-09.01-0540A; RTOP 324-02-01)
(NASA-CR-189735; NAS 1.26:189735) Avail: CASI HC A15/MF A03

SatCon Technology Corporation has completed a Small Business Innovation Research (SBIR) Phase 2 program to develop a Superconducting Large-Angle Magnetic Suspension (LAMS) for the NASA Langley Research Center. The Superconducting LAMS was a hardware demonstration of the control technology required to develop an advanced momentum exchange effector. The Phase 2 research was directed toward the demonstration for the key technology required for the advanced concept CMG, the controller. The Phase 2 hardware consists of a superconducting solenoid ('source coils') suspended within an array of nonsuperconducting coils ('control coils'), a five-degree-of-freedom positioning sensing system, switching power amplifiers, and a digital control system. The results demonstrated the feasibility of suspending the source coil. Gimballing (pointing the axis of the source coil) was demonstrated over a limited range. With further development of the rotation sensing system, enhanced angular freedom should be possible. Author (revised)

MISCIBILITY OF LUBRICANTS WITH REFRIGERANTS, PHASE 1
M. B. Pate, S. C. Zoz, and L. J. Berkenbosch Oct. 1992 58 p Prepared for Air-Conditioning and Refrigeration Technology Inst., Inc., Arlington, VA
(Contract DE-FG02-91CE-23810)
(DE93-014766-Phase-1; DOE/CE-23810/6) Avail: CASI HC A04/MF A01

Miscibility data have been obtained for a variety of non-CFC refrigerants and their potential lubricants. Ten different refrigerants and seven different lubricants were investigated. Experiments are being performed in two phases: phase 1, reported herein, focuses on performing screening tests for miscibility; and phase 2 consists of developing miscibility plots. The miscibility tests are being performed in a test facility consisting of a series of miniature test cells submerged in a constant temperature bath. The bath temperature can be precisely controlled over a temperature range of -50 to 90 C (-58 to 194 F). The test cells are constructed to allow for complete visibility of lubricant-refrigerant mixtures under all test conditions. DOE

EFFECT OF STABILIZATION ON THE RECYCLING OF POLYOLEFINS IN BLOW MOULDING
L. Pecora and R. W. DiRaddo Mar. 1993 41 p
(IMI-93RT-42400-1477-G; CTN-93-60820) Avail: CASI HC A03/MF A01

Extrusion blow molding experiments were conducted on two polyolefins to demonstrate two classes of degradation that occurs during the recycling or reprocessing of polymers. The two main degradation reactions that reduce product performance are chain scission and crosslinking. Polyethylene undergoes both chain scission and crosslinking, while polypropylene undergoes only chain scission. The degradation reactions cause a shift in the molecular weight distribution of the material in question. This material property shift generally affects parison swell and sag. The changes in parison formation behavior manifest themselves in the final blow molded part. The use of appropriate stabilizers can minimize these changes and render the final part acceptable. Also, the use of stabilization can allow an increase in the amount of recycled feedstock in the final product.

DYNAMIC FORMS. PART 1: FUNCTIONS
George Meyer and G. Allan Smith Aug. 1993 86 p
(RTOP 505-64-52)
(NASA-TP-3397; A-93078; NAS 1.60:3397) Avail: CASI HC A05/MF A01

The formalism of dynamic forms is developed as a means for organizing and systematizing the design control systems. The formalism allows the designer to easily compute derivatives to various orders of large composite functions that occur in flight-control design. Such functions involve many function-of-a-function calls that may be nested to many levels. The component functions may be multiaxis, nonlinear, and they may include rotation transformations. A dynamic form is defined as a variable together with its time derivatives up to some fixed but arbitrary order. The variable may be a scalar, a vector, a matrix, a direction cosine matrix, Euler angles, or Euler parameters. Algorithms for standard elementary functions and operations of scalar dynamic forms are developed first. Then vector and matrix operations and transformations between parameterization of rotations are developed in the next level in the hierarchy. Commonly occurring algorithms in control-system design, including inversion of pure feedback systems, are developed in the third level. A large-angle, three-axis attitude servo and other examples are included to illustrate the effectiveness of the developed formalism. All algorithms were implemented in FORTRAN code. Practical experience shows that the proposed formalism may significantly improve the productivity of the design and coding process.

APPLICATION OF SYMBOLIC AND ALGEBRAIC MANIPULATION SOFTWARE IN SOLVING APPLIED MECHANICS PROBLEMS
Wen-Lang Tsai and Noboru Kikuchi Aug. 1993 164 p Sponsored by NASA. Washington
(Contract NCA2-136)
(NASA-CR-4544; A-93112; NAS 1.26:4544) Avail: CASI HC A08/MF A02

As its name implies, symbolic and algebraic manipulation is an operational tool which not only can retain symbols throughout computations but also can express results in terms of symbols. This report starts with a history of symbolic and algebraic manipulators and a review of the literatures. With the help of selected examples, the capabilities of symbolic and algebraic manipulators are demonstrated. These applications to problems of applied mechanics are then presented. They are the application of automatic formulation to applied mechanics problems, application to a materially nonlinear problem (rigid-plastic ring compression) by finite element method (FEM) and application to plate problems by FEM. The advantages and difficulties, contributions, education, and perspectives of symbolic and algebraic manipulation are discussed. It is well known that there exist some fundamental difficulties in symbolic and algebraic manipulation, such as internal swelling and mathematical limitation. A remedy for these difficulties is proposed, and the three applications mentioned are solved successfully. For example, the closed from solution of stiffness matrix of four-node isoparametrical quadrilateral element for 2-D elasticity problem was not available before. Due to the work presented, the automatic construction of it becomes feasible. In addition, a new advantage of the application of symbolic and algebraic manipulation found is believed to be crucial in improving the efficiency of program execution in the future. This will substantially shorten the response time of a system. It is very significant for certain systems, such as missile and high speed aircraft systems, in which time plays an important role. A PERSPECTIVE ON AVS IN AN ENGINEERING SCIENCES ENVIRONMENT
M. W. Glass 1993 10 p Presented at the Application Visualization System (AVS) 1993 Users Group Meeting, Orlando, FL, 24-26 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-015011; SAND-93-1002C; CONF-9305168-3) Avail: CASI HC A02/MF A01

At Sandia National Laboratories, the Engineering Sciences Center has made a commitment to integrate the Application Visualization System (AVS) into our computing environment as the primary tool for scientific visualization. AVS will be used on an everyday basis by a broad spectrum of users ranging from the occasional computer user to AVS module developers.

Additionally, AVS will be used to visualize structured grid, unstructured grid, gridless, 1D, 2D, 3D, steady-state, transient, computational, and experimental data. The following is one user's perspective on how AVS meets this task. Several examples of how AVS is currently being utilized will be given along with some future directions. DOE

TRANSITION OF BUILDING ENERGY CONSUMPTION USING MULTI-INPUT, SINGLE-OUTPUT DYNAMIC MODEL

Jouko Pakanen Oct. 1992 46 p Sponsored by Ministry of Trade and Industry, Finland

(VTT-PUBS-116; ISBN-9-51-384234-7; ETN-93-94485) Avail: CASI HC A03/MF A01

A new method based upon online measurements of weather and other characteristic data is proposed. The method is capable of being used with building automation systems for failure detection. The method uses a multi input, single output dynamic model to predict the power fluctuation of the building. The model parameters are identified recursively by measuring the actual power, outdoor temperature, solar radiation, wind velocity, and indoor temperatures. The stochastic variations in power caused by occupants, equipment, and lights, can be included in the model. Measurements are taken once every half hour and are used to update the model parameters by a recursive extended least square algorithm. The identified model can be used to detect failures of equipment and systems. Verification of the method was accomplished using real weather data and the TARP computer program for the simulation of a town house and measurements collected from a real test building. ESA

AN EXPERIMENTAL STUDY ON THE EFFECT OF DIE GEOMETRY ON SWELL AND SAG IN THE PARISON EXTRUSION STAGE

L. Pecora and R. W. DiRaddo 15 Jan. 1993 34 p

(IMI-93RT-42400-1476-G; NRC-35347; CTN-93-60819) Avail: CASI HC A03/MF A01

Extrusion blow molding is the process of choice for production of many hollow parts. The process involves extrusion of a molten parison and inflation of the parison into the final part, whereupon the part is cooled and ejected. The ability to predict parison behavior is important as the parison dimensions govern the shape and thickness distribution of the final product. The effect of die geometry on parison swell and sag was studied in experiments employing three diverging dies of 3.5 cm diameter. Three mandrel angles were studied, being 25, 30, and 40 deg from the vertical. For each die angle, six gaps ranging from 0.3 to 2.0 mm were studied. The material used was a blow molding high density polyethylene grade. Preliminary results were obtained showing that the sag increases and the swell decreases as the die gap is increased. Swell was found to increase as die angle increased. The parison swell depends directly on the shear and extensional components in the die. The extensional component has a stronger effect than shear for a given level of stress. Author (CISTI)

FLEXIBILITY AND COSTS IN THE DESIGN PROCESS: A DECISION SUPPORT MODEL Ph.D. Thesis [FLEXIBILITEIT EN KOSTEN IN HET ONTERWERPPROCES: EEN BESLUITVORMINGONDERSTEUNEND MODEL]

Matthijs Prins 1992 166 p In DUTCH Sponsored by Netherlands Technology Foundation

(ISBN-9-06-814522-3; ETN-93-94047) Copyright Avail: CASI HC A08/MF A02

A decision support system was developed to increase flexibility and reduce costs in the design process of buildings. The most important terminology is presented as a set of building blocks to support the theory. Quality control is becoming increasingly more important in view of decreasing quantitative demands, increasing qualitative demands for differentiation in buildings, and shrinking financial means. Several terms related to the time dimension of buildings are discussed. Buildings are described in terms of systems (consisting of individual elements) and building oriented flexibility models. A financial economic calculating model for buildings is presented. The process model implements the flexibility model and the calculation method in a decision support system. Suggestions for further research are given. ESA

DOUBLE INLET PULSE TUBE CRYOCOOLER THEORY

Harold Mirels 2 Feb. 1993 27 p

(AD-A266832; ATR-93(8399)-2) Avail: CASI HC A03/MF A01

An analytical model has been developed for the performance of a double inlet pulse tube cryocooler employing a stepped piston compressor. Numerical results are presented as a function of the area ratio of the stepped piston. The double inlet pulse tube cryocooler is shown to have more refrigeration power than the corresponding single inlet device. However, the increased refrigeration power is achieved at the cost of reduced thermal efficiency. DTIC

THE MRIS FEASIBILITY STUDY

Robert T. Neece, Aubrey E. Cross (Research Triangle Inst., Hampton, VA.), and James H. Schrader (Research Triangle Inst., Hampton, VA.) Jun. 1993 72 p

(RTOP 505-64-12-04)

(NASA-TM-107763; NAS 1.15:107763) Avail: CASI HC A04/MF A01

The Microwave Reflectometer Ionization Sensor (MRIS) is an instrument being developed for use in detecting and ranging of electron density layers in the reentry plasma of a space transfer vehicle. The rationale for the selection of the Double Sideband Suppressed Carrier (DSBSC) system used in the feasibility study for the MRIS is presented. A 25 GHz single-oscillator system and a 220 GHz double-oscillator system are described. The 25 GHz system was constructed and tested in the laboratory

and test results are presented. As developed, the system employs a sideband spacing of 160 MHz. Based on an estimated electromagnetic wave velocity in the plasma, a round-trip phase shift measurement accuracy of +/- 7.6 degrees was required for the desired +/- 1/2 cm distance measurement accuracy. The interaction of parallel ground and reflecting planes produces interference that prevents the basic DSBSC system from meeting the accuracy goal so a frequency modulation was added to the system to allow averaging of the measured phase deviation. With an FM deviation of +/- 1 GHz, laboratory measurements were made for distances from 5 to 61 cm tip free space. Accounting for the plasma velocity factor, 82 percent of the data were equal to or better than the desired accuracy. Based on this measured result a sideband spacing to 250 MHz could be expected to yield data approximately 96 percent within the accuracy goal.

THE 24 GHz MEASUREMENTS OF 2.2 LAMBDA CONICAL HORN ANTENNAS ILLUMINATING A CONDUCTING SHEET
A. E. Cross (Research Triangle Inst., Hampton, VA.), R. E. Marshall (Research Triangle Inst., Hampton, VA.), C. P. Hearn, and R. T. Neece Jun. 1993 66 p
(RTOP 505-64-12-04)
(NASA-TM-109002; NAS 1.15:109002) Avail: CASI HC A04/MF A01

Monostatic reflection-coefficient magnitude, absolute value of Gamma, measurements occurring between a radiating horn and a metal reflecting plate are presented for a family of three 2.2 lambda diameter conical horn antennas. The three horns have different aperture phase deviations: 6 deg, 22.5 deg, and 125 deg. Measurements of the magnitude of absolute value of Gamma as a function of horn-plate separation (d) extend from an effective antenna aperture short (d = O) to beyond the far-field boundary (d = 2D(sup 2)/lambda, where D is the antenna diameter). Measurement data are presented with various physical environments for each of the horns. Measured scalar data are compared with theoretical data from two models, a numerical model for a circular waveguide aperture in a ground plane and a scalar diffraction theory model. This work was conducted in support of the development effort for a spaceborne multifrequency microwave reflectometer designed to accurately determine the distance from a space vehicle's surface to a reflecting plasma boundary. The metal reflecting plate was used to simulate the RF reflectivity of a critically dense plasma. The resulting configuration, a ground plane mounted aperture facing a reflecting plane in close proximity, produces a strong interaction between the ground plane and the reflecting plate, especially at integral half-wavelength separations. The transition coefficient is characterized by large amplitude variations. Author (revised)

RECURSIVE TIME-VARYING FILTER BANKS FOR SUBBAND IMAGE CODING
Mark J. T. Smith and Wilson C. Chung 1992 20 p
(Grants NAG5-2187; NSF MIP-91-16113)
(NASA-CR-193726; NAS 1.26:193726) Avail: CASI HC A03/MF A01

Filter banks and wavelet decompositions that employ recursive filters have been considered previously and are recognized for their efficiency in partitioning the frequency spectrum. This paper presents an analysis of a new infinite impulse response (IIR) filter bank in which these computationally efficient filters may be changed adaptively in response to the input. The filter bank is presented and discussed in the context of finite-support signals with the intended application in subband image coding. In the absence of quantization errors, exact reconstruction can be achieved and by the proper choice of an adaptation scheme, it is shown that IIR time-varying filter banks can yield improvement over conventional ones.

DIGITAL SOUND: THE SELECTION OF CRITICAL PROGRAMME MATERIAL AND PREPARATION OF RECORDINGS FOR CCIR TESTS ON LOW BIT-RATE CODECS
N. H. C. Gilchrist 1993 13 p
(BBC-RD-1993/1) Avail: Issuing Activity

A draft of a new recommendation on low bit-rate digital audio coding for broadcasting is in preparation within CCIR Study Group 10. As part of this work, subjective tests are being conducted to determine the preferred coding systems to be used in the various applications, and at which bit rates they should be used. The BBC has been contributing to the work by conducting preliminary listening tests to select critical program material, and by preparing recordings using this material for use by the CCIR's testing centers. ENVIRONMENTAL PROJECTS. VOLUME 15: ENVIRONMENTAL ASSESSMENT: PROPOSED 1-MEGAWATT RADAR TRANSMITTER AT THE MARS SITE
15 Oct. 1992 112 p
(Contract NAS7-918)
(NASA-CR-194098; JPL-Publ-87-4-Vol-15; NAS 1.26:194098) Avail: CASI HC A06/MF A02

The Goldstone Deep Space Communications Complex (GDSCC), located in the Mojave Desert about 64.5 km (40 mi) north of Barstow, California. and about 258 km (160 mi) northeast of Pasadena, California, is part of the National Aeronautics and Space Administration's (NASA's) Deep Space Network (DSN), one of the world's larger and more sensitive scientific telecommunications and radio navigation networks. The Goldstone Complex is managed, technically directed, and operated for NASA by the Jet Propulsion Laboratory (JPL) of the California Institute of Technology in Pasadena, California. Activities at the GDSCC support the operation of six parabolic dish antennas located at five separate sites called Deep Space Stations (DSS's). Four sites, named Echo, Mars, Uranus, and Apollo, are operational for space missions, while the remaining Venus Site is devoted to research and development activities. The Mars Site at the GDSCC contains two antennas: the Uranus antenna (DSS 15, 34 m) and the Mars antenna (DSS 14, 70 m). This present volume deals solely with the DSS-14 Mars antenna. The Mars antenna not only can act as a sensitive receiver to detect signals from spacecraft, but it also can be used in radar astronomy as a powerful transmitter to send out signals to probe the solar system. At present, the Mars antenna operates as a continuous-wave microwave system at a frequency of 8.51 GHz at a power level of 0.5 MW. JPL has plans to upgrade the Mars antenna to a power level of 1 MW. Because of the anticipated increase in the ambient levels of radio frequency radiation (RFR), JPL retained Battelle Pacific Northwest Laboratories (BPNL), Richland, Washington, to conduct an environmental assessment with respect to this increased RFR. This present volume is a JPL-expanded version of the BPNL report titled Environmental Assessment of the Goldstone Solar System Radar, which was submitted to JPL in Nov. 1991. This BPNL report concluded that the operation of the upgraded Mars antenna at the GDSCC, with its increased potential electromagnetic radiation hazards and interferences, would have no significantly adverse biological, physical, or socioeconomic effects on the environment. Thus, a Finding of No Significant Impact (FONSI) is appropriate in accordance with local, State, Federal, and NASA environmental rules and regulations. Author (revised)

ON THE END-TO-END COMMUNICATION PROBLEM IN UNRELIABLE NETWORKS M.S. Thesis
Adi Rosen Jun. 1990 33 p
(ITN-93-85188) Copyright Avail: Issuing Activity (Tel Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

Several protocols are presented to solve the end-to-end communication problem across an unreliable network. A protocol solving the problem is to

transmit from a sender to a receiver a sequence of data items input to the sender in an on-line manner. The difficulty in solving the problem in unreliable networks lies in the fact that one cannot rely on any specific path between the sender and the receiver to be operational. This work is centered around a simple method to deliver tokens between two communicating parties in an unreliable network. The token delivery protocol, called SLIDE, guarantees that, at any time, the network holds, at most, a bounded number of tokens and that no token is lost. When the network is full, the sender is prohibited from inputting more tokens until the receiver removes some. However, tokens are output at the receiver by the SLIDE, not necessarily in the same order in which they were input (i.e., the SLIDE is non-FIFO (first-in, first-out)). Basing ourselves on these properties of the SLIDE, we present a sequence of three end-to-end protocols. The first protocol is very simple, and its bit communication complexity per data item is O(n(exp 2)mD) bits, where n and m are the total number of nodes and links in the network, respectively, and D is the size in bits of the data item. However, it is data dependent, that is, the content of the data items is used by the protocol. The second protocol obtains the same bit communication complexity, but uses colors on the tokens to remove the data dependency of our first protocol. For large data items (D = Omega(nm logn)), where the performances of the first two algorithms degrade, we develop a third algorithm whose communication complexity is linear, O(nD) bits, per data item. This protocol combines techniques of the two first algorithms with the Information Dispersal Algorithm of Rabin. By collecting many data itsm of smaller size into one item of at least Omega(nm log n) bits, a linear (O(nD)) amortized bit communication complexity protocol can be obtained. Author (ISA)

LOWER BOUNDS ON TIME OF ARRIVAL ESTIMATION OF PULSE COMPRESSION WAVEFORMS M.S. Thesis

Israel Ben-Ivri Apr. 1990 237 p In HEBREW

(ITN-93-85189) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

The Weiss-Weinstein Lower Bound (WWLB), the Bellini-Tartara Lower Bound (BTLB), and the Kotelnikov inequality were applied to analysis of the attainable error in estimating the time of arrival (TOA) of a known (deterministic) signal embedded in additive Gaussian noise. The main advantage of the above bounds over the commonly used Cramer-Rao Lower Bound (CRLB) is that they can be applied to analysis of the estimation error over a wide range of signal to noise ratios (SNR), including threshold effects and ambiguity phenomena. The results of the above analysis were applied to TOA estimation using linear FM (frequency modulation) and Barker-13, which are typical pulse compression waveforms used in radar systems. For each signal, the estimation errors were evaluated for sampling and estimation of a baseband signal and of a bandpass signal. For baseband signals, the SNR domain comprises three regions: the local error domain in which the mean standard error (MSE) is described by the CRLB or an alternative; a threshold effect region where the MSE increases sharply; and a noise-dominated region. In the case of bandpass signals, two distinct threshold phenomena divide the SNR domain into five distinct regions: a Cramer-Rao region in which the MSE converges to CRLB; a region of transition from ambiguous estimation to local error estimation; an ambiguity dominated region in which an estimate can be obtained by using the envelope of the received signal; a threshold effect region in which there is a sharp increase in the MSE; and a noise dominated region in which the signal observations are essentially useless to estimation. Closed form analytical expressions for the threshold points SNR as functions of signal bandwidth, center frequency, and a-priori parameter domain, are obtained. We also derive lower bounds on the probability of occurrence of large estimation errors in the system. Comparison with the maximum likelihood (ML) estimator (that is the matched filter) reveals that the lower bounds are tight for a wide range of SNR conditions, and that the matched filter is near optimal above the threshold. A HYBRID FINITE ELEMENT-BOUNDARY INTEGRAL FOR THE ANALYSIS OF CAVITY-BACKED ANTENNAS OF ARBITRARY SHAPE

Jian Gong, John L. Volakis, A. C. Woo, and H. T. G. Wang Aug. 1993 36 p

(Contract NCA2-653)

(NASA-CR-193719; NAS 1.26:193719; UMICH-028918-5-T) Avail: CASI HC A03/MF A01

This is the final report on this project which was concerned with the analysis of cavity-backed antennas and more specifically spiral antennas. The project was a continuation of a previous analysis, which employed rectangular brick elements, and was, thus, restricted to planar rectangular patch antennas. A total of five reports were submitted under this project and we expect that at least four journal papers will result from the research described in these reports. The abstracts of the four previous reports are included. The first of the reports (028918-1-T) is over 75 pages and describes the general formulation using tetrahedral elements and the computer program. Report 028918-2-T was written after the completion of the computer program and reviews the capability of the analysis and associated software for planar circular rectangular patches and for a rectangular planar spiral. Measurements were also done at the University of Michigan and at Mission Research Corp. for the purpose of validating the software. We are pleased to acknowledge a partial support from Mission Research Corp. in carrying out the work described in this report. The third report (028918-3-T) describes the formulation and partial validation (using 2D data) for patch antennas on a circular platform. The 3D validation and development of the formulation for patch antennas on circular platforms is still in progress. The fourth report (028918-4-T) is basically an invited journal paper which will appear in the 'J. Electromagnetic Waves and Applications' in early 1994. It describes the application of the finite element method in electromagnetics and is primarily based on our work here at U-M. This final report describes the culmination of our efforts in characterizing complex cavity-backed antennas on planar platforms. The report describes for the first time the analysis of non-planar spirals and non-rectangular slot antennas as well as traditional planar patch antennas. The comparisons between measurements and calculations are truly impressive. Another unique aspect of this work is the incorporation of the FFT as part of the BiCG solver by overlaying a structured triangular mesh over the unstructured mesh. The implementation of this BiCG-FFT solution algorithm is important in minimizing the CPU and storage requirements. This final report will be submitted for publication in a refereed journal. INDUCED VOLTAGES AT AIR GAPS DUE TO ELECTROMAGNETIC FIELD CAUSED BY DIRECT AND INDIRECT LIGHTNING STROKES M.S. Thesis

David Berla Dec. 1991 116 p In HEBREW

(ITN-93-85203) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

During the last two decades there has been great development in power systems, electronic devices, and circuits, which are all sensitive to overvoltages caused by switching, induction, or atmospheric phenomena. In the present work, the induced voltages in a given configuration, due to direct and indirect lightning strokes were studied, from the point of view of the design requirements for economically and electrically optimal protective elements and devices. An approximate method is presented for calculating induced voltages, based on the electromagnetic field concept and using a system of compensating currents (CC). In the first part of the thesis, the basic equations of induced electric field strength components, due to current or charge waves, are introduced. These waves have a step-function character, and the mechanism of compensating currents, and their influence on the electromagnetic field are discussed. The second part of the thesis deals with the calculation of the induced voltages at air gaps in two geometrical models. The calculations are based on primary vectors describing the changes of the induced voltages at the air gap, due to the current on the main conductor and the compensating currents at the conducting loop and their mutual interactions. The main aim of this work was to develop a method, suitable for use with a personal computer, for calculating the induced voltage at an air gap, in a given geometrical model. Author (ISA)

COMPUTER CODE FOR SCATTERING FROM IMPEDANCE BODIES OF REVOLUTION. PART 3: SURFACE IMPEDANCE WITH s AND PHI VARIATION. ANALYTICAL AND NUMERICAL RESULTS

Piergiorgio L. E. Uslenghi, Sharad R. Laxpati, and Stephen F. Kawalko

Jun. 1993 89 p
(Grants NAG2-544; NSF ECS-93-0000N)
(NASA-CR-193396; NAS 1.26:193396; EML-93-6-1) Avail: CASI HC A05/MF A01

The third phase of the development of the computer codes for scattering by coated bodies that has been part of an ongoing effort in the Electromagnetics Laboratory of the Electrical Engineering and Computer Science Department at the University of Illinois at Chicago is described. The work reported discusses the analytical and numerical results for the scattering of an obliquely incident plane wave by impedance bodies of revolution with phi variation of the surface impedance. Integral equation formulation of the problem is considered. All three types of integral equations, electric field, magnetic field, and combined field, are considered. These equations are solved numerically via the method of moments with parametric elements. Both TE and TM polarization of the incident plane wave are considered. The surface impedance is allowed to vary along both the profile of the scatterer and in the phi direction. Computer code developed for this purpose determines the electric surface current as well as the bistatic radar cross section. The results obtained with this code were validated by comparing the results with available results for specific scatterers such as the perfectly conducting sphere. Results for the cone-sphere and cone-cylinder-sphere for the case of an axially incident plane were validated by comparing the results with the results with those obtained in the first phase of this project. Results for body of revolution scatterers with an abrupt change in the surface impedance along both the profile of the scatterer and the phi direction are presented. Author (revised)

EXACT RECONSTRUCTION ANALYSIS/SYNTHESIS FILTER BANKS WITH TIME-VARYING FILTERS
J. L. Arrowood, Jr. and M. J. T. Smith 1993 4 p
(Grants NAG5-2187; NSF MIP-91-16113)
(NASA-CR-193725; NAS 1.26:193725) Avail: CASI HC A01/MF A01

This paper examines some of the analysis/synthesis issues associated with FIR time-varying filter banks where the filter bank coefficients are allowed to change in response to the input signal. Several issues are identified as being important in order to realize performance gains from time-varying filter banks in image coding applications. These issues relate to the behavior of the filters as transition from one set of filter banks to another occurs. Lattice structure formulations for the time varying filter bank problem are introduced and discussed in terms of their properties and transition characteristics. Author (revised)

A fine time uplink synchronization scheme for a frequency hopped spread spectrum satellite communication system has been implemented in a hardware based laboratory experiment. The experiment is implemented using an analog surface acoustic wave spectrum analyzer. The synchronization scheme employed is the two-tone method. Measurements are taken using the two-tone method with and without bias reduction. Experimental results taken using the method without bias reduction lead to an inconsistent estimator for the actual timing error. The method with bias reduction produces a consistent estimator for the actual timing error. The experimental results from the method with bias reduction have been compared with simulated results generated from theory. The two results agree very well. Thus, the two-tone method is a viable method for fine time uplink synchronization. Author (CISTI)

A COMBINED ANALOGUE AND DIGITAL PULSE COMPRESSION SYSTEM USING LARGE TIME BANDWIDTH PRODUCT SIGNALS FOR USE IN SYNTHETIC APERTURE RADAR M.S. Thesis
Pushkar E. Godbole 5 Jul. 1989 148 p
(ISBN-0-315-54373-6; CTN-93-60723) Copyright Avail: Issuing Activity (Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC)

Pulse compression, widely used in modern radar systems, has the advantage in that it allows the use of long duration low-power pulses which facilitate low-power transmission. A synthetic aperture radar (SAR) pulse compression system able to compress very large time bandwidth product signals while still retaining high dynamic range capability and flexibility would be very advantageous. The possibility of implementing the compression in two stages is investigated, in which the first stage compression processing is done by an analog device followed by digital techniques in the second stage. Various signal coding methods were evaluated to determine those most suitable to the two-stage process, and various means of implementing the second stage were compared. A two-stage pulse compression system was then designed and built to generate arbitrarily coded expanded pulses with bandwidths in excess of 200 MHz. Its performance was evaluated in the presence of tone, noise, and jamming. It was shown that the two-stage pulse compression system exhibited greater resistance to quantizer saturation than a comparable digital system. The processing effort required to implement the compression using a digital adaptive matched filter was found to be slightly less than double that of a basic pulse compression system. Author (CISTI)

CONSTANT FALSE ALARM RATE (CFAR) DETECTION IN WEIBULL CLUTTER M.S. Thesis
Rafi Ravid Sep. 1990 93 p
(ITN-93-85190) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

A constant false alarm rate (CFAR) detector maintains a constant false alarm probability in the face of changes of the properties of the cause of the false alarms. False alarms in radar systems arise from receiver noise or clutter; clutter is considered. The CFAR processor maintains a constant false alarm rate by estimating the clutter level in a set of reference cells in the vicinity of the cell under test (CUT) and deciding on the basis of this information whether the CUT contains clutter or a target. Among the distribution functions which were fitted to the radar clutter were the Rayleigh distribution, the log-normal distribution, and the K distribution. The Weibull distribution was chosen, which has the cumulative distribution function: $F(x) = 1 - \exp(-(x/b)(\exp c))$ in which b is the scale parameter which controls the mean level of the variate, and c is the shape parameter which controls the skewness of the distribution. The Weibull distribution was found to describe land and sea clutter, especially for small resolution cell sizes and low depression angles. For the special case of $c = 2$, the Weibull distribution reduces to the Rayleigh distribution, which can be shown to be the distribution of a large number of scatterers of similar size. For c less than 2, the tail of the distribution becomes larger. Various CFAR algorithms which could be applied to the problem are discussed; various treatments using order-statistics (OS) CFAR processing were used. ISA

CANCELLATION OF MULTIPATH FOR MONOPULSE RADARS M.S. Thesis
Yuval Yehudar Jun. 1990 60 p
(ITN-93-85191) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

When radar is operated in tracking mode, loss of track caused by multipath can be easily avoided, but it is difficult to reduce the tracking error to the limits required for certain applications. Signal processing algorithms developed for phased array radars cannot be directly applied to monopulse radars, which have insufficient sensors to dissociate the multiple returns. Monopulse tracker operation and the multipath phenomenon are discussed, and some methods of dealing with it are summarized. A model is developed to represent the various problem parameters as simply as possible and a solution is based on the application to a monopulse radar of an algorithm used in phased arrays, in order to improve monopulse accuracy in the presence of multipath. A Maximum Likelihood Estimation (MLE) technique is suggested, in which sufficient independent data to resolve the estimation problem are obtained by sampling for longer periods, so allowing the relative phase between the direct and the indirect returns

to vary significantly. A comparative performance evaluation is presented and it is shown that use of the MLE technique can give an improvement by two orders of magnitude in the root-mean-square (RMS) error, compared with the usual processing technique, provided that phase coherence can be maintained over the data sampling time interval. BOUNDS ON TIME DELAY ESTIMATION GIVEN UNKNOWN SIGNAL SPECTRAL PARAMETERS M.S. Thesis

Shalom Tsruya Apr. 1991 164 p In HEBREW

(ITN-93-85194) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

The bounds on the time delay estimation error variance are well understood for the case of a Gaussian, stationary, flat-spectrum-source signal with known spectral density. This work presents a bound on time delay estimation error variance for the case of an arbitrary unknown spectrum. The bound presented in this work is based on the Barankin bound on the multi-dimensional parameter estimation problem. The Barankin bound has been used with some success to overcome the ambiguity problem. The source signal is modeled as a linear combination of flat spectrum signals with different unknown spectral levels. In this work we derived an expression for a lower bound on the time delay estimation error of a signal with N unknown spectral parameters (spectral levels). This is one of the few times that the Barankin bound multi-dimensional version has been applied to a practical problem. The threshold phenomenon in the Barankin bound for unknown parameters was considered in this work. The results are: 1. Generally, the estimation performance depends on the knowledge of the source spectral parameters. However, in most practical cases the degration in the performance of the time delay estimation as a result of the unknown spectral parameters is neglected. For large M (number of sensors) and small ratio, w(sub c) to w, we received significant degradation. 2. The achievable estimation performance depends strongly on the shape of the source spectrum. 3. Generally, the point at which the threshold occurs depends on knowledge of the source spectral parameters. In most practical cases the threshold location is insensitive to prior knowledge of the source spectra parameters. Author (ISA)

SIGNAL DESIGN FOR DATA COMMUNICATION THROUGH RAPIDLY VARYING LINEAR CHANNELS M.S. Thesis

Boaz Rippin Jan. 1992 94 p

(ITN-93-85195) Copyright Avail: Isuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

We consider the problem of data communication through an unknown rapidly varying linear channel, such as in mobile communication or underwater acoustic telemetry. The use of training sequences to identify the channel response at each transmission period may be impractical, owing to the fast varying nature of the channel. Therefore, as an alternative solution, we propose to use a signal design strategy in which we restrict the transmitted data stream to specific sequences. A generalized likelihood ratio test for detecting the transmitted sequence is developed, and the probability of detection is analysed. A bound on the detection performance is also developed. Based on that, we propose optimal and sub-optimal signal design strategies, one class of which consists of a new concept of all-pole, or autoregressive modulation of the data bits. Author (ISA)

THE PROPAGATION CHARACTERISTICS AND INSTABILITY PROPERTIES OF LOW-FREQUENCY ELECTROMAGNETIC WAVES IN THE IO PLASMA TORUS Ph.D. Thesis

Yi Mei 1992 304 p

Avail: Univ. Microfilms Order No. DA9310866

We explore the propagation characteristics and instability properties of low frequency electromagnetic waves in the Io plasma torus using a wave ray tracing technique HOTRAY. We evaluate the convective growth of ion cyclotron waves for each propagating frequency band below the gyrofrequency of protons f(sub H+) in the entire Io torus. We build up an analytical diffusive equilibrium density model (under some reasonable assumptions) which extrapolates the equatorial plasma conditions based on the in situ Voyager data analysis to high latitude regions along the field lines. This 2-D (in a meridian plane) analytical density model for Io plasma torus can be very useful for other computer simulation studies of the Io torus. The method to obtain this approximate analytical solution can be generalized to other multiple species plasma, e.g., the diffusive equilibrium distribution of ions in planetary ionosphere. A survey of wave excitation and propagation throughout the torus is presented and the sensitivities of the waves to the plasma parameters have been tested. The spatial regions for wave growth or damping are shown in a meridian plane for 6 is less than or equal to L is less than or equal to 10. The multispecies plasma in the torus limits L-mode wave propagation to several district bands in frequency. The top band waves with frequencies f(sub O+2) is less than f is less than f(sub H+) (approximately 10 Hz) are studied and compared with the previous works done by Thorne and Moses. Waves in this band may grow at intermediate latitude near L equivalent to 8, and the overall amplification is extremely sensitive to plasma parameters. The other bands with frequencies f less than f(sub O+) are examined here for the first time. Some of those waves (f equivalent to 0.5 Hz) can be very unstable near the equator at L equivalent to 7 - 10; this result is relatively independent of the plasma conditions. We have made predictions of possible unstable waves encountered by the ULYSSES spacecraft during its passage through Io torus high latitude regions on February, 1992. Dissert. Abstr.

ELECTRON BEAM PROBE MEASUREMENTS OF ELECTRIC FIELDS IN rf DISCHARGES Ph.D. Thesis

Arthur Hideyuki Sato 1992 221 p

Avail: Univ. Microfilms Order No. DA9305062

An electron beam diagnostic has been developed to measure small electric fields (less than 20 V/cm) in low pressure capacitive rf discharges. The electron beam diagnostic is described, and data are presented showing the existence of transient double layers at the sheath boundary, and evidence for a negative bulk plasma resistance. The electric field measurements motivated more careful measurements of the discharge current waveforms. The current waveforms together with the electric field measurements, provide evidence for negative bulk plasma resistance. The current measurements, in turn, allowed comparison between experimental discharge impedance data and results from a global discharge model. A modified version of the work of Misium et al. is presented. This includes a reformulation of the secondary electron contribution to the electron power balance, and incorporation of electrode asymmetry. The results of this model are compared to experimental results obtained from current and voltage measurements. The model predictions of current amplitude and phase shift at the first harmonic fit the experimental results surprisingly well for realistic values of the secondary emission coefficient. In particular, it is also shown how an additional electron energy deposition mechanism can result in a more linear current (I) to voltage (V) amplitude relation. Alternate explanations for a linear I-V dependence are discussed. A two-coupled-sheath model is presented that qualitatively describes current conduction through asymmetric discharges. Some results of this model are: (1) The time-averaged sheath voltages are somewhat insensitive to the shape of the current waveform, and hence much of what is known about the sheath voltage ratios remains true. (2) At moderate area ratios (less than 10) the current waveforms can maintain top-bottom symmetry if the driving voltage is allowed to distort slightly, and the external circuit prevents free circulation of the higher harmonic components of the current. The current waveforms will be skewed, distinguishing them from current waveforms of a symmetric discharge. (3) At higher area ratios (greater than 10) the top-bottom symmetry of the current waveform is difficult to preserve since the system is so close to being a single sheath. In this case, the conduction current spike remains prominent since it cannot be suppressed by distortions of the sheath voltage. Dissert. Abstr.

LOCALLY NON-UNIFORM FINITE-DIFFERENCE TIME DOMAIN WITH APPLICATION TO STEALTH, CROSSTALK, AND NARROW APERTURES

D. J. Riley Apr. 1993 104 p

(Contract DE-AC04-76DP-00789)

(DE93-013958; SAND-93-0735) Avail: CASI HC A06/MF A02

A technique to integrate a dense, locally non-uniform mesh into finite-difference time-domain (FDTD) codes is presented. The method is designed for the full-wave analysis of multi-material layers that are physically

thin, but perhaps electrically thick. Such layers are often used for the purpose of suppressing electromagnetic reflections from conducting surfaces. Throughout the non-uniform local mesh, average values for the conductivity and permittivity are used, where as variations in permeability are accommodated by splitting H-field line integrals and enforcing continuity of the normal B field. A unique interpolation scheme provides accuracy and late-time stability for mesh discontinuities as large as 1000 to 1. Application is made to resistive sheets, the absorbing Salisbury screen, crosstalk on printed circuit boards, and apertures that are narrow both in width and depth with regard to a uniform cell. Where appropriate, comparisons are made with the MoM code CARLOS and transmission-line theory. The hybrid mesh formulation has been highly optimized for both vector and parallel-processing on Cray Y-MP architectures. DOE

SCATTERING BY A GROOVE IN AN IMPEDANCE PLANE

Sunil Bindiganavale and John L. Volakis Sep. 1993 21 p

(Grant NAG1-1478)

(NASA-CR-193362; NAS 1.26:193362; UMA-030601-2-T) Avail: CASI HC A03/MF A01

An analysis of two-dimensional scattering from a narrow groove in an impedance plane is presented. The groove is represented by a impedance surface and the problem reduces to that of scattering from an impedance strip in an otherwise uniform impedance plane. On the basis of this model, appropriate integral equations are constructed using a form of the impedance plane Green's functions involving rapidly convergent integrals. The integral equations are solved by introducing a single basis representation of the equivalent current on the narrow impedance insert. Both transverse electric (TE) and transverse magnetic (TM) polarizations are treated. The resulting solution is validated by comparison with results from the standard boundary integral method (BIM) and a high frequency solution. It is found that the presented solution for narrow impedance inserts can be used in conjunction with the high frequency solution for the characterization of impedance inserts of any given width. ANTENNA PATTERN CONTROL USING IMPEDANCE SURFACES Final Report, 16 Sep. 1990 - 15 Sep. 1993

Constantine A. Balanis, Kefeng Liu, and Panayiotis A. Tirkas 15 Sep. 1993 122 p

(Grant NAG1-1183)

(NASA-CR-194517; NAS 1.26:194517; TRC-CAB-9308) Avail: CASI HC A06/MF A02

During the period of this research project, a comprehensive study of pyramidal horn antennas was conducted. Full-wave analytical and numerical techniques were developed to analyze horn antennas with or without impedance surfaces. Based on these full-wave analytic techniques, research was conducted on the use of impedance surfaces on the walls of the horn antennas to control the antenna radiation patterns without a substantial loss of antenna gain. It was found that the use of impedance surfaces could modify the antenna radiation patterns. In addition to the analytical and numerical models, experimental models were also constructed and they were used to validate the predictions. Excellent agreement between theoretical predictions and the measured data was obtained for pyramidal horns with perfectly conducting surfaces. Very good comparisons between numerical and experimental models were also obtained for horns with impedance surfaces. Author (revised)

METEOR FORWARD SCATTER STUDIES Final Report

A. R. Webster, J. Jones, and K. A. Ellis Apr. 1992 28 p

(DSIS-93-00382; CTN-93-60759) Avail: CASI HC A03

A meteor forward-scatter system was operated between sites located near Ottawa and London, Ontario to conduct studies on the occurrence of meteors which would be useful to the prediction of the performance of a forward scatter link. These included the rate of incoming meteors suitable for reflection and their radiant distributions, which will allow such predictions to be made. The system was put into operation in late Feb. 1991 and results covering the Mar.-Dec. 1991 period are presented, representing a total of about 80,000 individual meteor echoes. Graphs are included showing the diurnal and seasonal variations in meteor echoes and the radiant point of individual echoes from the measured angles of arrival. CISTI

SCATTERING OF REFLECTOMETER SIGNALS FROM RIPPLED SURFACES

G. D. Conway Jun. 1993 18 p

(PPL-138; CTN-93-60760) Avail: CASI HC A03/MF A01

Transverse coherent density fluctuations at the plasma cutoff layer are modeled by a rippled conducting surface. Two simulations are presented which give the reflectometer back-scattered power as functions of ripple wavelength, amplitude, and phase. Results from an experimental simulation of the STOR-M tokamak geometry and a numerical simulation using the Helmholtz integral and a paraxial Gaussian probe beam, agree in showing three ripple wavelength (L) sensitivity regions defined by beam radius (w) and reflectometer probe wavelength (lambda). Short wavelengths (L/lambda much less than 2w/lambda) experience large Bragg scattering. Long wavelengths (L/lambda much greater than 10w/lambda) experience no scattering. Intermediate wavelengths experience complex scattering with strong modulation of reflected power at twice ripple frequency. CISTI

USING A FOCAL-PLANE ARRAY TO ESTIMATE ANTENNA POINTING ERRORS

S. Zohar and V. A. Vilnrotter 25 Oct. 1991 84 p

(Contract NAS7-918)

(NASA-CR-194502; JPL-Publ-91-45; NAS 1.26:194502) Avail: CASI HC A05/MF A01

The use of extra collecting horns in the focal plane of an antenna as a means of determining the Direction of Arrival (DOA) of the signal impinging on it, provided it is within the antenna beam, is considered. Our analysis yields a relatively simple algorithm to extract the DOA from the horns' outputs. An algorithm which, in effect, measures the thermal noise of the horns' signals and determines its effect on the uncertainty of the extracted DOA parameters is developed. Both algorithms were implemented in software and tested in simulated data. Based on these tests, it is concluded that this is a viable approach to the DOA determination. Though the results obtained are of general applicability, the particular motivation for the present work is their application to the pointing of a mechanically deformed antenna. It is anticipated that the pointing algorithm developed for a deformed antenna could be obtained as a small perturbation of the algorithm developed for an undeformed antenna. In this context, it should be pointed out that, with a deformed antenna, the array of horns and its associated circuitry constitute the main part of the deformation-compensation system. In this case, the pointing system proposed may be viewed as an additional task carried out by the deformation-compensation hardware. Author (revised)

SUBMILLIMETER, MILLIMETER, AND MICROWAVE SPECTRAL LINE CATALOGUE, REVISION 3

H. M. Pickett, R. L. Poynter, and E. A. Cohen 1 Jun. 1992 224 p

(Contract NAS7-918)

(NASA-CR-194501; JPL-Publ-80-23-Rev-3; NAS 1.26:194501) Avail: CASI HC A10/MF A03

A computer-accessible catalog of submillimeter, millimeter, and microwave spectral lines in the frequency range between 0 and 10,000 GHz (i.e., wavelengths longer than 30 micrometers) is described. The catalog can be used as a planning or as an aid in the identification and analysis of observed spectral lines. The information listed for each spectral line includes the frequency and its estimated error, the intensity, the lower state energy, and the quantum number assignment. This edition of the catalog has information on 206 atomic and molecular species and includes a total of 630,924 lines. The catalog was constructed by using theoretical least square fits of published spectral lines to accepted molecular models. The associated predictions and their estimated errors are based upon the resultant fitted parameters and their covariances. Future versions of this catalog will add more atoms and molecules and update the present listings as new data appear. The catalog is available as a magnetic data tape recorded in card images, with one card image per spectral line, from the National Space Science Data Center, located at Goddard Space Flight Center. KALMAN FILTER BASED ARCHITECTURES FOR INTERFERENCE EXCISION

Brian Kozminchuk Dec. 1991 37 p

(DSIS-93-00034; DREO-RN-1118; CTN-93-60772; AD-A259650) Avail: CASI HC A03

A novel Kalman filtering approach is presented for the suppression of narrowband interference from direct sequence spread spectrum communications systems. The algorithm is based on the digital phase-locked loop Kalman filter. Because the interference is assumed to be much stronger than either the signal or the noise, the Kalman filter locks onto a function related to the interference. The net result is an estimate of the phase of the interference and its amplitude. The algorithm is characterized through computer simulation for the case of narrowband Gaussian noise interference. Examples of the phase- and envelope-tracking capabilities of the algorithm are presented, followed by bit error rate curves for interference bandwidths ranging from 0.5 to 5.0 percent of the chip rate of the spread spectrum signal. Three adaptive architectures are then described. The first is suitable for constant envelope interference; the second is a more general structure; and the third incorporates a decision feedback structure accompanied with a training sequence. A REVIEW OF ROBUST DETECTION

Eric April Oct. 1992 27 p

(DSIS-93-00400; DREO-TN-92-13; CTN-93-60749) Avail: CASI HC A03

A comprehensive survey is presented of the most important results published to date on robust detection. A robust detector is one for which good performance is obtained under nominal conditions while an acceptable level of performance is maintained for deviations of the observation statistics, within some allowable uncertainty class. The basic principles of robust detection are given and it is seen that the uncertainty model plays an important role in the derivation of the optimum scheme. For an eta contamination model, a censored version of the likelihood ratio constitutes the desired robust detector. The fundamental robust detection systems for various signal conditions are discussed and the asymptotic minimax robust detection approach is introduced in order to solve the problem for weak signals and large sample sizes. Some of the latest major contributions include results for dependent noise, asymmetric distributed noise, and adaptive robust detectors. Some concerns relating to the derivation of robust detection structures for continuous time processes are noted. Finally, recent topics such as the potential benefits of using the large deviations approach for robust detection are considered. Author (CISTI)

MUSIC AND MAXIMUM LIKELIHOOD USING A REFINED PROPAGATION MODEL: PERFORMANCE COMPARISON FOR RADAR LOW-ANGLE TRACKING

Eloi Bosse, Ross M. Turner, and Daniel Brookes (Advanced Information Technologies Corp., Nepean, Ontario.) Jan. 1992 48 p

(DREO-RN-1122; CTN-93-60766) Avail: CASI HC A03/MF A01

The performance of the MUSIC (multiple signal classification) algorithm and many other superresolution methods degrades severely with the highly correlated multipath signals encountered in radar low-angle tracking. This deficiency is overcome by deriving new versions of the MUSIC and maximum likelihood algorithms, which use a search vector based on a model of the specular multipath. The performance of these two approaches is then compared with that of the MUSIC algorithm using spatial smoothing. Monte Carlo simulations and experiments at X-band indicate that the use of a specular model combined with an array radar having frequency agility gives much more accurate tracking than do the conventional approaches. The experiments were conducted at a site on the shore of the North Sea, using corner reflectors mounted on poles inserted in the sea bed. Sea conditions varied from sea state one to five. THE DREO ELINT BROWSER UTILITY (DEBU) REFERENCE MANUAL

Barbara Ford and David Jones (Prior Data Sciences Ltd.) Apr. 1992 70 p

(DSIS-92-03900; DREO-RN-1130; CTN-93-60795) Avail: CASI HC A04/MF A01

An electronic intelligent database browsing tool called DEBU has been developed that allows databases such as ELP, Kilting, EWIR, and AFEWC to be reviewed and analyzed from a user-friendly environment on a personal computer. DEBU's basic function is to allow users to examine the contents of user-selected subfiles of user-selected emitters of user-selected databases. DEBU augments this functionality with support for selecting (filtering) and combining subsets of emitters by user-selected attributes such as name, parameter type, or parameter value. DEBU provides facilities for examining histograms and x-y plots of selected parameters, for doing ambiguity analysis and mode level analysis, and for generating and printing a variety of reports. A manual is provided for users of DEBU, including descriptions and illustrations of menus and windows. Author (CISTI)

DIGITAL QUADRATURE DEMODULATION FOR RADAR ESM APPLICATIONS

Robert Inkol and Ron Saper May 1992 60 p

(DREO-TN-92-10; CTN-93-60796; AD-A260166) Avail: CASI HC A04/MF A01

The feasibility of using digital techniques for coherent demodulation of wideband signals was investigated for application in radar electronic support measures systems. Several different design approaches and analysis methods were considered: a medium bandwidth design with simple Hilbert transformer, a medium bandwidth design with zero direct current offset, and a wide bandwidth matched response design with zero direct current offset. It was found that the processing requirements to achieve good accuracy for pulse and other wideband signals can be minimized through appropriate choice of intermediate frequency, the use of half-band finite impulse response filters, and the application of decimation. This suggests that an application specific integrated circuit implementation of a digital coherent demodulator should have potential cost and performance advantages over existing analog approaches. A STUDY OF METEOR SCATTER COMMUNICATIONS Final Report

A. R. Webster and J. Jones Apr. 1991 20 p

(Contract DSS-36001-9-3601-01-SS)

(DSIS-93-00151; CTN-93-60800) Avail: CASI HC A03

Communications over 500-2000 km by means of forward scatter from meteor trains is of increased interest due to improvements in both the available technology and the coding schemes and protocols. Studies were conducted to improve the knowledge of background statistics such as meteor rates and duration times. The primary objective was to develop a system capable of measuring accurately the direction of the echoes obtained from meteor forward scatter on a path of medium length. The distribution in amplitude and duration of echoes was also felt to be of importance and echo sampling methods and rates were to be consistent with this. The basic technique used involves phase measurements of the signals received on spaced antennas. Field experiments were conducted using a transmitter frequency of 48.7 MHz and two orthogonal receiving arrays, with transmitter and receiver located respectively in Ottawa and London, Ontario. Around 500 meteor echoes per day have been recorded since start of data collection in February 1991. The characteristics of representative echoes are illustrated. Two basic kinds of echoes were observed, a classic underdense echo where the radio wave penetrates the column of ionization left by the passage of the meteoroid and the overdense case with the echo persisting until the electron density falls to levels which allow penetration.

(Contract DSS-W7714-0-9383-01-SS)

(DSIS-93-00177; CRL-233; CTN-93-60802) Avail: CASI HC A05

A portable very high frequency (VHF) multipath measurement system

(PMMS) has been developed for use in performing field measurements and establishing a statistical data base for characterizing the propagation environment pertinent to VHF radio direction finding (DF). The problems related to radio DF which are to be investigated include the following: multipath effects due to assorted types of terrain, mutual coupling effects of the DF antenna array, analysis of the PMMS measurement data, and the construction of a multipath scattering model. The development of the digital DF system is described and simulation results are presented which will be used to support forthcoming VHF multipath studies. The calibration procedure for the PMMS system, the estimation of angle of arrival using a circular antenna array, the multipath model which simulates electromagnetic scattering from a rough surface, and radio wave propagation in forest environments are also described. ADAPTIVE SIGNAL PROCESSING TESTBED Final Report
Hugh A. Parliament 10 Sep. 1991 15 p
(Contract DREO-W7714-0-9504)
(DSIS-93-00258; CTN-93-60807) Avail: CASI HC A03

The design and implementation of a system for the acquisition, processing, and analysis of signal data is described. The initial application for the system is the development and analysis of algorithms for excision of interfering tones from direct sequence spread spectrum communication systems. The system is called the Adaptive Signal Processing Testbed (ASPT) and is an integrated hardware and software system built around the TMS320C30 chip. The hardware consists of a radio frequency data source, digital receiver, and an adaptive signal processor implemented on a Sun workstation. The software components of the ASPT consists of a number of packages including the Sun driver package; UNIX programs that support software development on the TMS320C30 boards; UNIX programs that provide the control, user interaction, and display capabilities for the data acquisition, processing, and analysis components of the ASPT; and programs that perform the ASPT functions including data acquisition, despreading, and adaptive filtering. The performance of the ASPT system is evaluated by comparing actual data rates against their desired values. A number of system limitations are identified and recommendations are made for improvements. CISTI

ADAPTIVE SIGNAL PROCESSING TESTBED: SOFTWARE DESIGN SPECIFICATION
Hugh A. Parliament Jun. 1990 82 p
(Contract DREO-W7714-0-9504)
(DSIS-93-00259; CTN-93-60808) Avail: CASI HC A05/MF A01

The Adaptive Signal Processing Testbed is a system for the analysis and characterization of adaptive filtering algorithms used for the excision of interfering tones from direct sequence spread spectrum communications systems. The design specification for the software to be developed for this testbed is described. The testbed system is divided into a number of subsystems and the required software for each subsystem is presented. The control and data flow between the subsystem as well as a modular breakdown of the software is provided. The online component of the host software provides all the control, monitoring, and storage functions for the embedded software system that resides on the bus in the host computer, a Sun workstation. The online component consists of five separate modules: user interface, graphical display, central processing, data storage, and development. The offline, or post-processing, component of the host software provides sophisticated statistical and spectral analysis of the data stored on disk. An interactive environment is provided for the user to develop customized analysis methods. CISTI

CURRENT DISTRIBUTION TOMOGRAPHY FOR DETERMINATION OF INTERNAL CURRENT DENSITY DISTRIBUTIONS
P. C. Gailey 1993 9 p Presented at the Applied Computational Electromagnetic Society (ACES) Meeting, Monterey, CA, 24 Mar. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015463; CONF-9303182-1) Avail: CASI HC A02/MF A01

A method is presented for the determination of current densities inside a cylindrical object using measurements of the magnetic fields outside the object. The cross section of the object is discretized with the current assumed constant over each defined region. Magnetic fields outside the object are related to the internal current densities through a geometry matrix which can be inverted to yield a solution for the current densities in terms of the measured fields. The primary limitation of this technique results from singularities in the geometry matrix that arise due to cylindrical symmetry of the problem. Methods for circumventing the singularities to obtain information about the distribution of current densities are discussed. This process of current distribution tomography is designed to determine internal body current densities using measurements of the external magnetic field distribution. It is non-invasive, and relatively simple to implement. Although related to a more general study of magnetic imaging which has been used to investigate endogenous currents in the brain and other parts of the body, it is restricted to currents either applied directly or induced by exposure to an external field. The research is related to public concern about the possibility of health effects resulting from exposure to power frequency electric and magnetic fields. DOE

TRELLIS CODING WITH CONTINUOUS PHASE MODULATION (CPM) FOR SATELLITE-BASED LAND-MOBILE COMMUNICATIONS Final Report, 7 May 1987 - 7 Aug. 1989
Sep. 1989 297 p
(Contract NAS7-1003; SBIR-14.05-6455)
(NASA-CR-191325; NAS 1.26:191325) Avail: CASI HC A13/MF A03

This volume of the final report summarizes the results of our studies on the satellite-based mobile communications project. It includes: a detailed analysis, design, and simulations of trellis coded, full/partial response CPM signals with/without interleaving over various Rician fading channels; analysis and simulation of computational cutoff rates for coherent, noncoherent, and differential detection of CPM signals; optimization of the complete transmission system; analysis and simulation of power spectrum of the CPM signals; design and development of a class of Doppler frequency shift estimators; design and development of a symbol timing recovery circuit; and breadboard implementation of the transmission system. Studies prove the suitability of the CPM system for mobile communications.

ANALYSIS OF MICROSTRIP PATCH ANTENNAS WITH NONZERO SURFACE RESISTANCE
David G. Shively and M. C. Bailey Washington Aug. 1993 18 p Sponsored in part by Army Communications Electronics Command, Fort Monmouth, NJ
(RTOP 505-64-20-54)
(NASA-TP-3362; CECOM-TR-93-E-2; L-17219; NAS 1.60:3362) Avail: CASI HC A03/MF A01

The scattering properties of a microstrip patch antenna with nonzero surface impedance are examined. The electric field integral equation for a current element on a grounded dielectric slab is developed for a rectangular geometry by using Galerkin's technique with subdomain piecewise linear basis functions. The integral equation includes a resistive boundary condition on the surface of the patch. The incident field on the patch is expressed as a function of incidence angle. The resulting system of equations is then solved for the unknown current modes on the patch, and the radar cross section is calculated for a given scattering angle. Theoretical results in the form of radar cross section as a function of frequency are compared with results measured at the NASA Langley Research Center. Author

ADVANCED COMMUNICATIONS ESM SYSTEM (ACES) TESTBED: INTEGRATION STUDY
Rick E. Ingram and Hugh A. Parliament 14 Jul. 1992 62 p
(DSIS-93-00345; CTN-93-60744) Avail: CASI HC A04

The Advanced Communications Electronic Support Measures (ESM) System (ACES) testbed is being developed to provide a research environment to explore new techniques in a variety of ESM-related functions. ACES receives radio signals from the outside world, performs signal of interest detection and analysis, and provides results in the form of audio signals, data for post-processing, or sensory input data to the Data Fusion and Correlation Techniques Testbed. The components of the ACES testbed are detailed: a wide-band signal source based on a digital receiver; a wide-band analysis subsystem to analyze the input from the signal source;

a narrow band signal extractor which reduces the bandwidth of the wide-band data; a narrow band analysis subsystem; the ACES system controller; and a real-time data storage subsystem. The current status of each component is given along with options and suggestions for those components not yet specified. The proposed strategy for ACES integration and interfaces between the various components are described. The interfacing requirements can be satisfied by developing three custom microprocessor boards. An interim solution for system integration that provides a limited set of functions for a fixed application is also proposed. A task-by-task breakdown, time schedule, and cost summary for the integration plan is included. CISTI

SIMULATION OF DOWNLINK SYNCHRONIZATION FOR A FREQUENCY-HOPPED SATELLITE COMMUNICATION SYSTEM
Lyle Wagner Apr. 1992 37 p
(DSIS-93-00477; DREO-TN-92-9; CTN-93-60745; AD-A259606) Avail: CASI HC A03

Frequency hopped spread spectrum satellite communication systems provide robust communications resilient to many types and levels of jamming. Unfortunately, this increase in resilience is offset by an increase in complexity while establishing the communication link, termed synchronization. A two-step downlink synchronization method is examined, involving the transmission by satellite of synchronization hops that are modulated with a synchronization code and are received by the ground terminal where the two-step algorithm is implemented. The first step is the envelope detection of the sync hops, coarse time synchronization. When the terminal is confident that the coarse synchronization process is complete, the second step (fine time synchronization) is activated. This involves correlating a downlink sync hop with an internally generated reference sync hop to obtain an accurate time estimate. Additionally, a prediction of the frequency offset can be made to fine-tune the local oscillator. Computer simulations were made of the synchronization process using synchronization codes of varying lengths to verify the algorithm. These simulations demonstrate that the proposed algorithm is capable of operating under severe jamming conditions and is compatible with the corresponding communication link. Author (CISTI)

STOCHASTIC PERFORMANCE MODELING AND EVALUATION OF OBSTACLE DETECTABILITY WITH IMAGING RANGE SENSORS
Larry Matthies and Pierrick Grandjean 15 Mar. 1993 23 p
(Contract NAS7-918)
(NASA-CR-194510; JPL-Publ-93-11; NAS 1.26:194510) Avail: CASI HC A03/MF A01

Statistical modeling and evaluation of the performance of obstacle detection systems for Unmanned Ground Vehicles (UGVs) is essential for the design, evaluation, and comparison of sensor systems. In this report, we address this issue for imaging range sensors by dividing the evaluation problem into two levels: quality of the range data itself and quality of the obstacle detection algorithms applied to the range data. We review existing models of the quality of range data from stereo vision and AM-CW LADAR, then use these to derive a new model for the quality of a simple obstacle detection algorithm. This model predicts the probability of detecting obstacles and the probability of false alarms, as a function of the size and distance of the obstacle, the resolution of the sensor, and the level of noise in the range data. We evaluate these models experimentally using range data from stereo image pairs of a gravel road with known obstacles at several distances. The results show that the approach is a promising tool for predicting and evaluating the performance of obstacle detection with imaging range sensors. Author (revised)

CHARACTERISTICS OF THE AMATEUR RADIO MEANS OF THE ARSENE SATELLITE [CARACTERISTIQUES DES MOYENS DE TRAFIC RADIOAMATEUR DU SATELLITE ARSENE]
Andre Cuisin Nov. 1992 41 p In FRENCH
(CNES-NT-131; ETN-93-93978) Copyright Avail: CASI HC A03/MF A01

The Arsene (Ariane amateur radio satellite for space education) satellite is designed to provide amateur radio telecommunications services. Its equatorial orbit (20,000/36,000 km/0 deg) provides some 50 hours of continuous visibility by a radioamateur station. This radioamateur network will transmit in Packet AX25, SSB, and TTY modes and will provide voice transmission. In addition to the usual Very High Frequencies (VHF) and Ultra High Frequencies (VHF), an S-band spacecraft/ground link are included. Packet and S-band Arsene telemetry reception will enable users to monitor spacecraft behavior in orbit. Accessible to universities, colleges of further education, and technical colleges, these facilities will contribute to the teaching of space related subjects. ESA

ADAPTIVE SIGNAL PROCESSING TESTBED: VME-BASED DSP BOARD MARKET SURVEY
Rick E. Ingram Apr. 1992 19 p
(Contract DREO-W7714-0-9504)
(DSIS-93-00274; CTN-93-60812) Avail: CASI HC A03

The Adaptive Signal Processing Testbed (ASPT) is a real-time multiprocessor system utilizing digital signal processor technology on VMEbus based printed circuit boards installed on a Sun workstation. The ASPT has specific requirements, particularly as regards to the signal excision application, with respect to interfacing with current and planned data generation equipment, processing of the data, storage to disk of final and intermediate results, and the development tools for applications development and integration into the overall EW/COM computing environment. A prototype ASPT was implemented using three VME-C-30 boards from Applied Silicon. Experience gained during the prototype development led to the conclusions that interprocessor communications capability is the most significant contributor to overall ASPT performance. In addition, the host involvement should be minimized. Boards using different processors were evaluated with respect to the ASPT system requirements, pricing, and availability. Specific recommendations based on various priorities are made as well as recommendations concerning the integration and interaction of various tools developed during the prototype implementation. ENVELOPE AND INSTANTANEOUS FREQUENCY ESTIMATION OF NARROWBAND MODULATED SIGNALS
Rene Lamontagne Dec. 1991 53 p
(DREO-TN-92-3; CTN-93-60736) Avail: CASI HC A04/MF A01

Generally, the transmission of a message signal in the radio frequency spectrum is accomplished by modulating the phase (corresponding to the instantaneous frequency) and amplitude of a carrier. The signal envelope and instantaneous frequency constitute, therefore, useful features to characterize the different modulation types. These two features are thus often used in an automatic modulation recognition system. The implementation of a digital algorithm for signal envelope and instantaneous frequency estimation is discussed. The modulation types involved are amplitude modulation, frequency modulation (FM), single sideband suppressed carrier, on-off keying or amplitude shift keying, frequency shift keying, and binary phase shift keying. The outputs of the envelope detector and frequency discriminator are presented for two types of signal: noisy (signal to noise ratio (SNR) of 25 dB) and very noisy (SNR = 5 dB). Also discussed are the following: the advantages of a median filter over a standard lowpass filter, the use of Lagrange's formula to estimate derivatives of discrete signals, and the effect of the noise at the outputs of the envelope detector and frequency discriminator. It appears that the output of the FM discriminator contains numerous click-noise spikes when the signal is very noisy, and it is difficult to distinguish among the modulation types. Author (CISTI)

ADAPTIVE SIGNAL PROCESSING TESTBED SIGNAL EXCISION SOFTWARE: USER'S MANUAL
Hugh A. Parliament May 1992 25 p
(Contract DREO-W7714-0-9504)
(DSIS-93-00260; CTN-93-60809) Avail: CASI HC A03

The Adaptive Signal Processing Testbed (ASPT) signal excision software is a set of programs that provide real-time processing functions for the excision of interfering tones from a live spread-spectrum signal as well as off-line functions for the analysis of the effectiveness of the excision technique. The processing functions provided by the ASPT signal excision software are real-time adaptive filtering of live data, storage to disk, and file sorting and conversion. The main off-line analysis function is bit error determination. The purpose of the software is to measure the effectiveness of an adaptive filtering algorithm to suppress interfering or jamming signals in a spread spectrum signal environment. A user manual for the software is provided, containing information on the different software components available to perform signal excision experiments: the real-time excision software, excision host program, file processing utilities, and despreading and bit error rate determination software. In addition, information is presented describing the excision algorithm implemented, the real-time processing framework, the steps required to add algorithms to the system, the processing functions used in despreading, and description of command sequences for post-run analysis of the data. ADAPTIVE SIGNAL PROCESSING TESTBED APPLICATION SOFTWARE: USER'S MANUAL
Hugh A. Parliament May 1992 20 p
(Contract DREO-W7714-0-9504)
(DSIS-93-00261; CTN-93-60810) Avail: CASI HC A03

The Adaptive Signal Processing Testbed (ASPT) application software is a set of programs that provide general data acquisition and minimal processing functions on live digital data. The data are obtained from a digital input interface whose data source is the DAR4000 digital quadrature receiver that receives a phase shift keying signal at 21.4 MHz intermediate frequency. The data acquisition software is used to acquire raw unprocessed data from the DAR4000 and store it on disk in the Sun workstation based ASPT. File processing utilities are available to convert the stored files for analysis. The data evaluation software is used for the following functions: acquisition of data from the DAR4000, conversion to IEEE format, and storage to disk; acquisition of data from the DAR4000, power spectrum estimation, and on-line plotting on the graphics screen; and processing of disk file data, power spectrum estimation, and display and/or storage to disk in the new format. A user's guide is provided that describes the acquisition and evaluation programs along with how to acquire, evaluate, and use the data. CISTI

A COMPARISON OF RECURSIVE LEAST SQUARES AND KALMAN FILTERING EXCISORS FOR SWEPT TONE INTERFERENCE
Brian Kozminchuk Oct. 1992 26 p
(DSIS-93-00362; DREO-TN-92-14; CTN-93-60758; AD-A259913) Avail: CASI HC A03

A Kalman filtering approach is presented which is used for filtering narrow band interference out of direct sequence spread spectrum signals. The approach is based on the digital phase-locked loop Kalman filter and is close to optimum insofar as demodulating a frequency modulated type of interferer. Because the interference is assumed to be much stronger than either the signal or the noise, the Kalman filter locks onto the interference and produces estimates of its phase and envelope. The algorithm is compared, through computer simulation, with the recursive least squares lattice algorithm for the case of a swept tone interferer. Examples of the phase- and envelope- tracking capabilities of the algorithm are presented, followed by bit error rate curves for the case of an interferer of bandwidth equal to 20 percent of the chip rate of the spread spectrum signal. The results show that with proper selection of the Kalman filter parameters, the Kalman filter excisor can outperform the recursive least squares algorithm by 2 dB. It is suggested that performance could perhaps be improved further by using a higher order Kalman filter to remove the residual phase-tracking error produced by the second order Kalman filter. TESTING VARIOUS TIME-FREQUENCY DISTRIBUTION TECHNIQUES
Robert Klepko and Khanh N. Tran (Ottawa Univ., Ontario.) Nov. 1992 55 p
(DREO-TN-92-17; CTN-93-60738) Avail: CASI HC A04/MF A01

Two time-frequency distributions (TFD's), the Choi-Williams and the Wigner-Ville, are described and tested to illustrate how each technique can resolve stationary and nonstationary signals in both time and frequency domains. The results were compared to those obtained with the standard method used for spectral analysis, short-time discrete Fourier transformation. The tests were performed with discrete simulated sinusoidal signals as well as real signals representing the temporal radar backscatter collected from a synthetic aperture radar. The general properties of the backscatter are the fading in and out of narrowband signals and shifting of signal frequency through time as a result of scatterer motion. Using a TFD allows analysis of the Doppler frequency history of the scatterers located on a target of interest. The major conclusion from the tests performed with real signals is that the Choi-Williams distribution is preferred over both the Wigner-Ville distribution and discrete Fourier transformation as a result of improved signal to noise ratios in the spectral domain. Subroutines used to compute the various distributions are appended. Author (CISTI)

MULTIPLE-SYMBOL DIFFERENTIAL DETECTION OF DPSK WITH FREQUENCY OFFSET
Martin Turgeon Dec. 1991 49 p
(DREO-TN-92-5; CTN-93-60739) Avail: CASI HC A03/MF A01

A ground terminal (GT) simulator for an extremely high frequency satellite communications system is being developed. The GT demodulator uses multiple symbol differential detection of differential phase-shift keying (MSDPSK), a demodulation technique which estimates the phase reference of a differential phase shift keying (DPSK) modulated, burst signal over a sequence of N symbols. The bit error rate (BER) performance is investigated and the simulation results are presented. The BER performance of MSDPSK is shown to approach that of coherently detected DPSK for large values of N. The effects of frequency offset are also examined. For a specific amount of frequency uncertainty, there is an optimum sequence size N that yields the best BER performance. For example, given a burst size of 13 bits and a frequency offset up to one fiftieth of the bit rate, the optimum sequence size is in the range of three to five bits.

I/Q DEMODULATION OF RADAR SIGNALS WITH CALIBRATION AND FILTERING
Jim P. Y. Lee Dec. 1991 67 p
(DREO-RN-1119; CTN-93-60740; AD-A260153) Avail: CASI HC A04/MF A01

A simple in-phase quadrature (I/Q) demodulator architecture which can measure the amplitude, phase, and instantaneous frequency of radar signals is examined. This architecture has the potential for radar electronic support measure applications where wide instantaneous bandwidth and simple algorithms for extracting the modulation characteristics of radar signals are required. This I/Q architecture can meet the requirement by splitting an incoming signal into its in-phase and quadrature components using analog hardware. However, in practice, there are amplitude and phase imbalances between the two components and direct current offsets, which can introduce large systematic errors in the measurements. Novel techniques are presented which can greatly reduce the systematic errors and improve the accuracy of the measurement. A time domain analysis of the systematic errors is given. A calibration technique which can be used to correct for the imbalances and offsets is discussed. The effect of noise on the accuracy of the measurement is also examined. Finally, a post-processing technique employing moving averages is presented. The technique is shown to be effective for improving the output signal to noise ratio and reducing systematic errors. EWTEST SIGNAL EXCISION TESTBED: SYSTEM EVALUATION
Rick E. Ingram Jan. 1992 11 p
(DSIS-93-00346; CTN-93-60752) Avail: CASI HC A03

A digital signal processing testbed is being developed to provide a platform for the development of spread spectrum signal excision algorithms. The testbed performs real-time acquisition and signal excision on the acquired data. It also provides a post-processing capability for algorithm evaluation. The system is to be implemented using the VMEC30 boards from Applied Silicon, installed in a Sun workstation. The proposed design of the real-time portion of the system is analyzed with respect to general system structure, host/VMEC30 communications, inter-VMEC30 communications, and task distribution. Specific recommendations are made for overcoming the observed limitations of the system, as well as recommendations regarding testbed extensibility and future enhancements.

BRIDGING THE GAP BETWEEN THE RAYLEIGH AND THOMSON LIMITS FOR VARIOUS CONVEX BODIES
G. R. Fournier and B. T. N. Evans Jan. 1993 31 p
(DSIS-93-00613; DREV-R-4692-93; CTN-93-60843) Avail: CASI HC A03

If a particle is geometrically and optically small enough, approximate formulae usually called the Rayleigh approximation can be found for the extinction and scattering efficiencies as well as the phase function of these particles. If the particle is still geometrically small but optically very large, the Thomson approximation results. Often, however, a geometrically small particle may be neither optically small nor very large, creating a gap. A transform of Mie coefficients and their series expansion is demonstrated that bridges this gap for spheres and infinite cylinders. This transform generalizes, in an approximate form, to other convex bodies when a Rayleigh or Thomson-like series can be obtained. The results of a comparison between the newly obtained series and the exact codes for spheres and spheroids is also presented. This research will aid in the design and performance analysis of potential new obscurants using high refractivity materials. The electromagnetic extinction through rain, smoke, or other nonspherical atmospheric aerosols can also be evaluated by this approach, an essential first step in the evaluation of the performance of all electro-optical systems.

ELECTRICAL CHARACTERIZATION OF THE JET A(SUB 2) ANTENNA: COMPARISON OF MODEL WITH MEASUREMENTS WADE, T.
P. M. Ryan, R. H. Goulding, V. Bhatnagar, A. Kaye, and T. Wade 1993 5 p Presented at the 10th Topical Conference on Radio Frequency Power in Plasmas, Boston, MA, 1-3 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-012964; CONF-9304112-8) Avail: CASI HC A01/MF A01

The JET experiment is replacing its previous (A1) antennas with upgraded designs (A2) for its upcoming 'pumped diverter' operation. These antennas are more directional than the previous two-strap A1 antennas when operated as a phased array. The frequency range is 23 to 57 MHz. A full-scale low power 'flat' mockup was tested at JET; strap lengths were adjusted to give balanced operation with resonance at 42 MHz. A second mockup module, differing only slightly from the original, was subsequently fabricated and both modules were sent to ORNL for additional measurements and to test the operation of the power compensator circuit. There are benefits to using a transmission line model to characterize coupled antenna systems, primarily in the ease of incorporating the antennas into the overall analysis of the transmission, tuning, and matching system. The characteristics of the array under arbitrary phasing are also needed for the design, analysis, and control of the power compensator. There are aspects of the JET A2 antenna geometry that differ considerably from previously modeled cases. Each transmission line feeds two poloidally-stacked straps connected in parallel. The parallel straps present different electrical loads at the match point due to geometrical differences. Currents in one section of the strap influence other sections of the same strap as well as in neighboring straps due to internal inductive coupling. The lengths of the inner and outer straps differ; moreover, the inner straps are fed from ports located behind the outer straps, resulting in increased coupling between the inner and outer straps due to the long feed lines and in greater disparity between the electrical loads presented at the inner and outer feed ports. The present effort is to determine whether a more general coupled transmission line model can characterize the array response with sufficient accuracy for the purpose of design and analysis.

RADIO METRIC ERRORS DUE TO MISMATCH AND OFFSET BETWEEN A DSN ANTENNA BEAM AND THE BEAM OF A TROPOSPHERE CALIBRATION INSTRUMENT
R. P. Linfield and J. Z. Wilcox *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 1-13 (For primary document see N94-14369 02-32)
(RTOP 310-10-60-93-01)
Avail: CASI HC A03/MF A03

Two components of the error of a troposphere calibration measurement were quantified by theoretical calculations. The first component is a beam mismatch error, which occurs when the calibration instrument senses a conical volume different from the cylindrical volume sampled by a Deep Space Network (DSN) antenna. The second component is a beam offset error, which occurs if the calibration instrument is not mounted on the axis of the DSN antenna. These two error sources were calculated for both delay (e.g., VLBI) and delay rate (e.g., Doppler) measurements. The beam mismatch error for both delay and delay rate drops rapidly as the beamwidth of the troposphere calibration instrument (e.g., a water vapor radiometer or an infrared Fourier transform spectrometer) is reduced. At a 10-deg elevation angle, the instantaneous beam mismatch error is 1.0 mm for a 6-deg beamwidth and 0.09 mm for a 0.5-deg beam (these are the full angular widths of a circular beam with uniform gain out to a sharp cutoff). Time averaging for 60-100 sec will reduce these errors by factors of 1.2-2.2. At a 20-deg elevation angle, the lower limit for current Doppler observations, the beam-mismatch delay rate error is an Allan standard deviation over 100 sec of 1.1 x 10(exp -14) with a 4-deg beam and 1.3 x 10(exp -l5) for a 0.5-deg beam. A 50-m beam offset would result in a fairly modest (compared to other expected error sources) delay error (less than or equal to 0.3 mm for 60-sec integrations at any elevation angle is greater than or equal to 6 deg). However, the same offset would cause a large error in delay rate measurements (e.g., an Allan standard deviation of 1.2 x 10(exp -14) over 100 sec at a 20-deg elevation angle), which would dominate over other known error sources if the beamwidth is 2 deg or smaller. An on-axis location is essential for accurate troposphere calibration of delay

rate measurements. A half-power beamwidth (for a beam with a tapered gain profile) of 1.2 deg or smaller is desired for calibration of all types of radio metrics. A water-vapor radiometer calibration beam of this size with very low sidelobes would require a clear aperture antenna with a diameter of at least 1.5 m if the primary water vapor sensing channel were in the 20-22 GHz range. IMPROVED TREATMENT OF GLOBAL POSITIONING SYSTEM FORCE PARAMETERS IN PRECISE ORBIT DETERMINATION APPLICATIONS **c04**

Y. Vigue, S. M. Lichten, R. J. Muellerschoen, G. Blewitt, and M. B. Heflin *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 14-20 (For primary document see N94-14369 02-32)
(RTOP 310-10-61-84-02)
Avail: CASI HC A02/MF A03

Data collected from a worldwide 1992 experiment were processed at JPL to determine precise orbits for the satellites of the Global Positioning System (GPS). A filtering technique was tested to improve modeling of solar-radiation pressure force parameters for GPS satellites. The new approach improves orbit quality for eclipsing satellites by a factor of two, with typical results in the 25- to 50-cm range. The resultant GPS-based estimates for geocentric coordinates of the tracking sites, which include the three DSN sites, are accurate to 2 to 8 cm, roughly equivalent to 3 to 10 nrad of angular measure. USE OF GLOBAL POSITIONING SYSTEM MEASUREMENTS TO DETERMINE GEOCENTRIC COORDINATES AND VARIATIONS IN EARTH ORIENTATION **c04**

R. P. Malla (Sterling Software, Inc., Pasadena, CA.), S.-C. Wu, and S. M. Lichten *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 21-33 (For primary document see N94-14369 02-32)
(RTOP 310-10-61-84-02)
Avail: CASI HC A03/MF A03

Geocentric tracking station coordinates and short-period Earth-orientation variations can be measured with Global Positioning System (GPS) measurements. Unless calibrated, geocentric coordinate errors and changes in Earth orientation can lead to significant deep-space tracking errors. Ground-based GPS estimates of daily and subdaily changes in Earth orientation presently show centimeter-level precision. Comparison between GPS-estimated Earth-rotation variations, which are the differences between Universal Time 1 and Universal Coordinated Time (UT1-UTC), and those calculated from ocean tide models suggests that observed subdaily variations in Earth rotation are dominated by oceanic tidal effects. Preliminary GPS estimates for the geocenter location (from a 3-week experiment) agree with independent satellite laser-ranging estimates to better than 10 cm. Covariance analysis predicts that temporal resolution of GPS estimates for Earth orientation and geocenter improves significantly when data collected from low Earth-orbiting satellites as well as from ground sites are combined. The low Earth GPS tracking data enhance the accuracy and resolution for measuring high-frequency global geodynamical signals over time scales of less than 1 day. Author

FAILURE MODES OF REDUCED-ORDER ORBIT DETERMINATION FILTERS AND THEIR REMEDIES **c13**

D. J. Scheeres *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 34-42 (For primary document see N94-14369 02-32)
(RTOP 310-10-63-50-00)
Avail: CASI HC A02/MF A03

Ways in which failure can occur in reduced-order, orbit determination filter, error covariance calculations are discussed. In the context of this article, reduced-order filters denote nonoptimal filters which include fixed levels of uncertainty in some parameters of the measurement models or in the spacecraft dynamical model which are not explicitly estimated in the filter equations. Failure is defined as an increase in the orbit determination covariance with the addition of data or as an unreasonable growth in the covariance with time, i.e., nonasymptotic behavior of the covariance. Some simple, known cases of failure are discussed along with their traditional remedies. In addition, more modern remedies are discussed which are currently under development at the Jet Propulsion Laboratory. The article first describes the known problems of reduced-order filters when they are employed for orbit determination, and their traditional remedies. Then, having defined these, the relevancy and desirability of the more modern remedies are made apparent. Author (revised)

CAMMATIC: AN APPROACH TO IMPROVE DSS 13 ANTENNA GRAVITY-LOADING PERFORMANCE

R. Levy and D. Strain (Planning Research Corp., Pasadena, CA.) *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 43-50 (For primary document see N94-14369 02-32)
(RTOP 310-20-65-86-04)
Avail: CASI HC A02/MF A03

Corrective actuator forces are applied to the DSS 13 antenna structure to improve its accuracy. These forces are calibrated according to the antenna elevation requirements. The calibration is derived from accurate field measurements and is not subject to the errors that result from computer modeling. A successful demonstration provided significant antenna surface improvement. An improvement of 0.6 to 1 dB is predicted. Author (revised)

A cryogenically cooled Ka-band (33.6-GHz), seven-element front-end array for the DSN was built and tested. This system uses seven high electron mobility transistor (HEMT) low-noise amplifiers cooled by a two-stage closed-cycle refrigerator. All system components from the polarizers to the output isolators are cooled to a physical temperature between 18 and 35 K. The noise temperatures of the individual elements range from 64 to 84 K over a 2.75-GHz bandwidth. Author

Avail: CASI HC A02/MF A03

Two superconducting Tl-Ca-Cu-Ba-O bandpass filters were fabricated for JPL by Superconductor Technologies Incorporated, Santa Barbara, California. The filters were designed to operate at 2.3 GHz (S-band) with a 0.5-dB bandwidth of 60 MHz and at 8.45 GHz (X-band) with a 0.5-dB bandwidth of 150 MHz. The structure selected for both filters incorporates half-wavelength thin-film resonators in a stripline configuration. The S-band filter uses an edge-coupled interdigital design and the X-band filter uses an end-coupled design. The insertion loss and the noise-temperature contribution were measured at 12 K for both filters. Author (revised)

Avail: CASI HC A02/MF A03

In Reed-Solomon codes and all other maximum distance separable codes, there is an intrinsic relationship between the size of the symbols in a codeword and the length of the codeword. Increasing the number of symbols in a codeword to improve the efficiency of the coding system thus requires using a larger set of symbols. However, long Reed-Solomon codes are difficult to implement and many communications or storage systems cannot easily accommodate an increased symbol size, e.g., M-ary frequency shift keying (FSK) and photon-counting pulse-position modulation demand a fixed symbol size. A technique for sharing redundancy among many different Reed-Solomon codewords to achieve the efficiency attainable in long Reed-Solomon codes without increasing the symbol size is described. Techniques both for calculating the performance of these new codes and for determining their encoder and decoder complexities is presented. These complexities are usually found to be substantially lower than conventional Reed-Solomon codes of similar performance. Author (revised)

ESTIMATING THE SIZE OF HUFFMAN CODE PREAMBLES
R. J. McEliece and T. H. Palmatier (California Inst. of Tech., Pasadena.) *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 90-95 (For primary document see N94-14369 02-32)
(RTOP 310-30-71-83-02)
Avail: CASI HC A02/MF A03

Data compression via block-adaptive Huffman coding is considered. The compressor consecutively processes blocks of N data symbols, estimates source statistics by computing the relative frequencies of each source symbol in the block, and then synthesizes a Huffman code based on these estimates. In order to let the decompressor know which Huffman code is being used, the compressor must begin the transmission of each compressed block with a short preamble or header file. This file is an encoding of the list n = (n(sub 1), n(sub 2)....,n(sub m)), where n(sub i) is the length of the Hufffman codeword associated with the ith source symbol. A simple method of doing this encoding is to individually encode each n(sub i) into a fixed-length binary word of length log(sub 2)l, where l is an a priori upper bound on the codeword length. This method produces a maximum preamble length of mlog(sub 2)l bits. The object is to show that, in most cases, no substantially shorter header of any kind is possible.

ENHANCED DECODING FOR THE GALILEO S-BAND MISSION
S. Dolinar and M. Belongie *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 96-111 (For primary document see N94-14369 02-32)
(RTOP 314-30-61-02-07)
Avail: CASI HC A03/MF A03

A coding system under consideration for the Galileo S-band low-gain antenna mission is a concatenated system using a variable redundancy Reed-Solomon outer code and a (14,1/4) convolutional inner code. The 8-bit Reed-Solomon symbols are interleaved to depth 8, and the eight 255-symbol codewords in each interleaved block have redundancies 64, 20, 20, 20, 64, 20, 20, and 20, respectively (or equivalently, the codewords have 191, 235, 235, 235, 191, 235, 235, and 235 8-bit information symbols, respectively). This concatenated code is to be decoded by an enhanced decoder that utilizes a maximum likelihood (Viterbi) convolutional decoder; a Reed Solomon decoder capable of processing erasures; an algorithm for declaring erasures in undecoded codewords based on known erroneous symbols in neighboring decodable words; a second Viterbi decoding operation (redecoding) constrained to follow only paths consistent with the known symbols from previously decodable Reed-Solomon codewords; and a second Reed-Solomon decoding operation using the output from the Viterbi redecoder and additional erasure declarations to the extent possible. It is estimated that this code and decoder can achieve a decoded bit error rate of 1 x 10(exp 7) at a concatenated code signal-to-noise ratio of 0.76 dB. By comparison, a threshold of 1.17 dB is required for a baseline coding system consisting of the same (14,1/4) convolutional code, a (255,223) Reed-Solomon code with constant redundancy 32 also interleaved to depth 8, a one-pass Viterbi decoder, and a Reed Solomon decoder incapable of declaring or utilizing erasures. The relative gain of the enhanced system is thus 0.41 dB. It is predicted from analysis based on an assumption of infinite interleaving that the coding gain could be further improved by approximately 0.2 dB if four stages of Viterbi decoding and four levels of Reed-Solomon redundancy are permitted. Confirmation of this effect and specification of the optimum four-level redundancy profile for depth-8 interleaving is currently being done. Author (revised)

STABILITY MEASUREMENTS OF THE RADIO SCIENCE SYSTEM AT THE 34-m HIGH-EFFICIENCY ANTENNAS
T. T. Pham, J. C. Breidenthal, T. K. Peng, S. F. Abbate, and S. T. Rockwell *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 112-139 (For primary document see N94-14369 02-32)
(RTOP 314-40-41-11-06)
Avail: CASI HC A03/MF A03

From 1991 to 1993 the fractional frequency stability of the operational Radio Science System was measured at DSS's 15, 45, and 65. These stations are designed to have the most stable uplink and downlink equipment in the Deep Space Network (DSN). Some measurements were performed when the antenna was moving and the frequency was ramped. The stability, including contributions of all elements in the station except for the antenna and the hydrogen maser, was measured to be 0.3 to 1.3 x 10(exp -15) when the frequency was fixed, and 0.6 to 6.0 x 10(exp -15) when the frequency was ramped (sample interval, 1000 sec). Only one measurement out of fifteen exceeded specification. In all other cases, when previous measurements on the antenna and the hydrogen maser were added, a total system stability requirement of 5.0 x 10(exp -15) as met. In addition, ambient temperature was found to cause phase variation in the measurements at a rate of 5.5 deg of phase per deg C. Author (revised)

PERFORMANCE RESULTS OF A DIGITAL TEST SIGNAL GENERATOR **c33**
B. O. Gutierrez-Luaces, M. Marina, and B. Parham (OAO Corp., Los Angeles, CA.) *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 140-153 (For primary document see N94-14369 02-32)
(RTOP 314-40-41-11-06)
Avail: CASI HC A03/MF A03

Performance results of a digital test signal-generator hardware-demonstration unit are reported. Capabilities available include baseband and intermediate frequency (IF) spectrum generation, for which test results are provided. Repeatability in the setting of a given signal-to-noise ratio (SNR) when a baseband or an IF spectrum is being generated ranges from 0.01 dB at high SNR's or high data rates to 0.3 dB at low data rates or low SNR's. Baseband symbol SNR and carrier SNR (Pc/No) accuracies of 0.1 dB were verified with the built-in statistics circuitry. At low SNR's that accuracy remains to be fully verified. These results were confirmed with measurements from a demodulator synchronizer assembly for the baseband spectrum generation, and with a digital receiver (Pioneer 10 receiver) for the IF spectrum generation. Avail: CASI HC A03/MF A03

Effectively planning the use and evolution of the Deep Space Network (DSN) is a complex problem involving many parameters. The tool that models many of these complexities, yet requires simple structured inputs and provides concise easy-to-understand metrics to aid in the planning process is discussed. The tool, PC4CAST, is used for both load forecasting (predicting how well planned that DSN resources meet expected demand) and as a decision support tool in the capacity-planning process (determining the relative benefits of capacity expansion options). It is now in use in the TDA Planning Office, has been used in numerous studies, and is also being used by the JPL Multimission Operations System Office (MOSO) as an integral part of Resource Allocation Team activities. Experience using the tool has helped to identify additional requirements that will further improve the planning process, which can be met by future PC4CAST versions. Author

ASYNCHRONOUS TRANSFER MODE LINK PERFORMANCE OVER GROUND NETWORKS
E. T. Chow and R. W. Markley *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 185-191 (For primary document see N94-14369 02-32)
(RTOP 316-30-19-41-04)
Avail: CASI HC A02/MF A03

The results of an experiment to determine the feasibility of using asynchronous transfer mode (ATM) technology to support advanced spacecraft missions that require high-rate ground communications and, in particular, full-motion video are reported. Potential nodes in such a ground network include Deep Space Network (DSN) antenna stations, the Jet Propulsion Laboratory, and a set of national and international end users. The experiment simulated a lunar microrover, lunar lander, the DSN ground communications system, and distributed science users. The users were equipped with video-capable workstations. A key feature was an optical fiber link between two high-performance workstations equipped with ATM interfaces. Video was also transmitted through JPL's institutional network to a user 8 km from the experiment. Variations in video depending on the networks and computers were observed, the results are reported.

Avail: CASI HC A03/MF A03

Uplink optical communication to a deep-space vehicle was demonstrated. In the Galileo Optical Experiment (GOPEX), optical transmissions were beamed to the Galileo spacecraft by Earth-based transmitters at the Table Mountain Facility (TMF), California, and Starfire Optical Range (SOR), New Mexico. The demonstration took place over an eight-day period (9 Dec. through 16 Dec. 1992) as Galileo receded from Earth on its way to Jupiter, and covered ranges from 1-6 million km. At 6 million km (15 times the Earth-Moon distance), the laser beam transmitted from TMF eight days after Earth flyby covered the longest known range for transmission and detection. Author (revised)

CALIBRATION OF THE RECEIVER CHANNEL FOR THE GOPEX PRECURSOR EXPERIMENTS
A. Biswas *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 205-212 (For primary document see N94-14369 02-32)
(RTOP 315-91-60-10-03)
Avail: CASI HC A02/MF A03

Calibration measurements for the cooled (253 K) photomultiplier tube (PMT) detector, used on the receiver channel of the transmit/receive (T/R) switch for GOPEX, were conducted in the laboratory. A pulsed frequency-doubled neodymium:yttrium-aluminum-garnet (Nd:YAG) laser was used to direct 532-mn light on the PMT. By monitoring the energy per pulse of the light incident on the PMT, the minimum number of photons detected could be determined. These results agreed with the photon flux back-calculated from the PMT output waveform. Approximately 700 incident photons arriving during a temporal pulse width of approximately 65 nsec were detected with a signal-to-noise ratio (SNR) of approximately 1. Other receiver channel characteristics, such as PMT dark currents, optical transmission, and interference filter sensitivity to angle of light incidence, were also measured. Author (revised)

DATA ANALYSIS FOR GOPEX IMAGE FRAMES
B. M. Levine, K. S. Shaik, and T.-Y. Yan *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 213-229 (For primary document see N94-14369 02-32)
(RTOP 315-91-60-10-03)
Avail: CASI HC A03/MF A03

The data analysis based on the image frames received at the Solid State Imaging (SSI) camera of the Galileo Optical Experiment (GOPEX) demonstration conducted between 9-16 Dec. 1992 is described. Laser uplink was successfully established between the ground and the Galileo spacecraft during its second Earth-gravity-assist phase in December 1992. SSI camera frames were acquired which contained images of detected laser pulses transmitted from the Table Mountain Facility (TMF), Wrightwood, California, and the Starfire Optical Range (SOR), Albuquerque, New Mexico. Laser pulse data were processed using standard image-processing techniques at the Multimission Image Processing Laboratory (MIPL) for preliminary pulse identification and to produce public release images. Subsequent image analysis corrected for background noise to measure received pulse intensities. Data were plotted to obtain histograms on a daily basis and were then compared with theoretical results derived from applicable weak-turbulence and strong-turbulence considerations. Processing steps are described and the theories are compared with the experimental results. Quantitative agreement was found in both turbulence regimes, and better agreement would have been found, given more received laser pulses. Future experiments should consider methods to reliably measure low-intensity pulses, and through experimental planning to geometrically locate pulse positions with greater certainty. TELESCOPE POINTING FOR GOPEX
W. M. Owen, Jr. *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 230-235 (For primary document see N94-14369 02-32)
(RTOP 315-91-60-10-03)
Avail: CASI HC A02/MF A03

In order for photons emitted by the GOPEX lasers to be detected by Galileo's camera, the telescopes at Table Mountain Observatory and Starfire Optical Range had to be pointed in the right direction within a tolerance less than the beam divergence. At both sites nearby stars were used as pointing references. The technical challenge was to ensure that the transmission direction and the star positions were specified in exactly the same coordinate system; given this assurance, neither the uncertainty in the star catalog positions nor the difficulty in offset pointing was expected to exceed the pointing error budget. The correctness of the pointing scheme was verified by the success of GOPEX. Author

HRMS SKY SURVEY WIDEBAND FEED SYSTEM DESIGN FOR DSS 24 BEAM WAVEGUIDE ANTENNA
P. H. Stanton, P. R. Lee, and H. F. Reilly *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 316-326 (For primary document see N94-14369 02-32)
(RTOP 314-30-69-40-06)
Avail: CASI HC A03/MF A03

The High-Resolution Microwave Survey (HRMS) Sky Survey project will be implemented on the DSS 24 beam waveguide (BWG) antenna over the frequency range of 2.86 to 10 GHz. Two wideband, ring-loaded, corrugated feed horns were designed to cover this range. The horns match the frequency-dependent gain requirements for the DSS 24 BWG system. The performance of the feed horns and the calculated system performance of DSS 24 are presented. Author

THE FLIGHT PERFORMANCE OF THE GALILEO ORBITER USO
D. D. Morabito, T. P. Krisher, and S. W. Asmar *In its* The Telecommunications and Data Acquisition Report 15 Aug. 1993 p 327-345 (For primary document see N94-14369 02-32)
(RTOP 314-40-31-30-26; RTOP 889-54-62-01-00)
Avail: CASI HC A03/MF A03

Results are presented from an analysis of radio metric data received by the DSN stations from the Galileo spacecraft using an Ultrastable Oscillator (USO) as a signal source. These results allow the health and performance of the Galileo USO to be evaluated, and are used to calibrate this Radio Science instrument and the data acquired for Radio Science experiments such as the Red-shift Observation, Solar Conjunction, and Jovian occultations. Estimates for the USO-referenced spacecraft-transmitted frequency and frequency stability were made for 82 data acquisition passes conducted between launch (October 1989) and November 1991. Analyses of the spacecraft-transmitted frequencies show that the USO is behaving as expected. The USO was powered off and then back on in August 1991 with no adverse effect on its performance. The frequency stabilities measured by Allan deviation are consistent with expected values due to thermal wideband noise and the USO itself at the appropriate time intervals. The Galileo USO appears to be healthy and functioning normally in a reasonable manner. Author (revised)

FEASIBILITY STUDY OF A SYNTHESIS PROCEDURE FOR ARRAY FEEDS TO IMPROVE RADIATION PERFORMANCE OF LARGE DISTORTED REFLECTOR ANTENNAS Semiannual Status Report

W. L. Stutzman, K. Takamizawa, P. Werntz, J. LaPean, and B. Shen Oct. 1993 13 p

(Grant NAG1-859)

(NASA-CR-194491; NAS 1.26:194491; SATCOM-93-15) Avail: CASI HC A03/MF A01

The manpower on this effort was reduced during this reporting period. Activity in the past six months is summarized. The Type 1 antenna is complete and documentation is in final phases. The Type 2 antenna design is complete and a journal article was prepared and was accepted for publication in EEE Transactions on Antennas and Propagation. The spherical antenna configurations are complete and a journal article will appear in the June 1993 issue of EEE Transactions on Antennas and Propagation. In addition, a patent for the spherical antenna is being pursued. The final current activity is that of optimization techniques and they are approaching completion as well. The Tri-Reflector synthesis code (TSAP) was put into user friendly format. A user's guide (Report 93-13) was written and distributed to LaRC. Work continues on EASY7. EASY7 is a user friendly code used to create an input file to GRASP7. Author (revised)

IONOSPHERIC EFFECTS ON A WIDE-BANDWIDTH, POLARIMETRIC, SPACE-BASED, SYNTHETIC-APERTURE RADAR

B. C. Brock Jan. 1993 67 p

(Contract DE-AC04-76DP-00789)

(DE93-015084; SAND-92-1967) Avail: CASI HC A04/MF A01

The earth's ionosphere consists of an ionized plasma which will interact with any electromagnetic wave propagating through it. The interaction is particularly strong at vhf and uhf frequencies but decreases for higher microwave frequencies. These interaction effects and their relationship to the operation of a wide-bandwidth, synthetic-aperture, space-based radar are examined. Emphasis is placed on the dispersion effects and the polarimetric effects. Results show that high-resolution (wide-bandwidth) and high-quality coherent polarimetrics will be very difficult to achieve below 1 GHz. DOE

TRANSFORM CODING FOR SPACE APPLICATIONS

Daniel Glover Oct. 1993 11 p Proposed for presentation at the Computing in Aerospace 9 Conference, San Diego, CA, 19-21 Oct. 1993; sponsored by AIAA

(RTOP 144-10-10)

(NASA-TM-106362; E-8160; NAS 1.15:106362; AIAA Paper 93-4670)

Avail: CASI HC A03/MF A01

Data compression coding requirements for aerospace applications differ somewhat from the compression requirements for entertainment systems. On the one hand, entertainment applications are bit rate driven with the goal of getting the best quality possible with a given bandwidth. Science applications are quality driven with the goal of getting the lowest bit rate for a given level of reconstruction quality. In the past, the required quality level has been nothing less than perfect allowing only the use of lossless compression methods (if that). With the advent of better, faster, cheaper missions, an opportunity has arisen for lossy data compression methods to find a use in science applications as requirements for perfect quality reconstruction runs into cost constraints. This paper presents a review of the data compression problem from the space application perspective. Transform coding techniques are described and some simple, integer transforms are presented. The application of these transforms to space-based data compression problems is discussed. Integer transforms have an advantage over conventional transforms in computational complexity. Space applications are different from broadcast or entertainment in that it is desirable to have a simple encoder (in space) and tolerate a more complicated decoder (on the ground) rather than vice versa. Energy compaction with new transforms are compared with the Walsh-Hadamard (WHT), Discrete Cosine (DCT), and Integer Cosine (ICT) transforms. Author

PROCEEDINGS OF THE SEVENTEENTH NASA PROPAGATION EXPERIMENTERS MEETING (NAPEX 17) AND THE ADVANCED COMMUNICATIONS TECHNOLOGY SATELLITE (ACTS) PROPAGATION STUDIES MINIWORKSHOP

Faramaz Davarian, ed. 1 Aug. 1993 329 p Meeting held in Pasadena, CA, 14-15 Jun. 1993

(Contract NAS7-918)

(NASA-CR-194096; JPL-Publ-93-21; NAS 1.26:194096) Avail: CASI HC A15/MF A03

The NASA Propagation Experimenters Meeting (NAPEX) is convened annually to discuss studies made on radio wave propagation by investors from domestic and international organizations. NAPEX 17 was held on 15 June 1993. The meeting was organized into two technical sessions. The first session was dedicated to slant path propagation studies and experiments. The second session focused on propagation studies for mobile and personal communications. Preceding NAPEX 17, the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop was held on 14 June 1993 to review ACTS propagation activities with emphasis on ACTS experiments status and data collection, processing, and exchange. For individual titles, see N94-14655 through N94-14678.

N94-14655*# Jet Propulsion Lab., California Inst. of Tech., Pasadena.

OPENING REMARKS: CURRENT AND FUTURE ACTIVITIES

Faramaz Davarian *In its* Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 1-11 (For primary document see N94-14654 02-32)

Avail: CASI HC A03/MF A03

It is our custom to present the Propagation Program's recent accomplishments and future plans at the onset of a NAPEX meeting. A summary is presented. The data analysis phase of the U.S. Olympus Campaign is nearing its end. The final report will be published by Virginia Tech by midsummer 1993. The report will comprise measurement analysis for 12 months. It will include monthly and annual attenuation statistics and statistics on scintillation effects. A number of prediction models will be presented. The ACTS propagation experiment preparations are moving forward as expected. The mobile/personal channel characterization efforts continued during the last year. Data collected by the University of Texas in 1992 are being analyzed and will become available by September 1993. We have recently started a study to characterize LEO mobile/personal channels. Topics such as indoor reception, tree shadowing, blockage, and delay spread will be investigated. These results will become available in one to two years from now. We have also collected Ka-band mobile data using Olympus 20 GHz beacon transmissions. The University of Texas has already collected five years of low-elevation angle, 11GHz propagation data. The work on database for propagation models has progressed very well. The first release is ready, and the participants of this meeting will receive a copy of the software. We had an active year where CCIR is concerned. An input document on land mobile satellite system (LMSS) propagation models was submitted to the U.S. national committee and was approved and sent to Geneva. Author (revised)

NEW CHALLENGES IN PROPAGATION RESEARCH IN THE US

Faramaz Davarian *In its* Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagati on Studies Miniworkshop 1 Aug. 1993 p 13-24 (For primary document see N94-14654 02-32)

Avail: CASI HC A03/MF A03

Earth/space propagation research in the U.S. is tied to new developments in satellite communications. In spite of the fiber optics competition for trunked point-to-point communications, a host of emerging services are discovering the great potential of satellites for wireless communications. The application of satellites for radio communications appears to grow with a rapid pace in the areas of thin-route and mobile/personal communications. An important factor influencing the future of satellite communications is the congestion of the spectral slots at Ku- and lower bands. This heavy usage of the spectrum gives rise to conflicts among the users and consequently forces regulatory organizations to relocate frequency assignments, a decision that, for obvious reasons, is unpopular

with the relocated service. Because of this frequency shortage, frequencies in Ka- and higher spectral bands are currently viewed as good candidates for Earth/space communications in the future. Therefore, new challenges in propagation research in the U.S. include the characterization of mobile/personal links and the investigation of higher bands for satellite communications. The plans and the challenges of the propagation research in the U.S. are briefly reviewed. Author (revised)

USER NEEDS FOR PROPAGATION DATA

Thomas M. Sullivan *In* JPL, Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 27-30 (For primary document see N94-14654 02-32)

Avail: CASI HC A01/MF A03

New and refined models of radio signal propagation phenomena are needed to support studies of evolving satellite services and systems. Taking an engineering perspective, applications for propagation measurements and models in the context of various types of analyses that are of ongoing interest are reviewed. Problems that were encountered in the signal propagation aspects of these analyses are reviewed, and potential solutions to these problems are discussed. The focus is on propagation measurements and models needed to support design and performance analyses of systems in the Mobile-Satellite Service (MSS) operating in the 1-3 GHz range. These systems may use geostationary or non-geostationary satellites and Frequency Division Multiple Access (FDMA), Time Division Multiple Access Digital (TDMA), or Code Division Multiple Access (CDMA) techniques. Many of the propagation issues raised in relation to MSS are also pertinent to other services such as broadcasting-satellite (sound) at 2310-2360 MHz. In particular, services involving mobile terminals or terminals with low gain antennas are of concern. Author (revised)

STATISTICAL RESULTS FROM THE VIRGINIA TECH PROPAGATION EXPERIMENT USING THE OLYMPUS 12, 20, AND 30 GHz SATELLITE BEACONS

Warren L. Stutzman, A. Safaai-Jazi, Timothy Pratt, B. Nelson, J. Laster, and H. Ajaz *In* JPL, Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 33-45 (For primary document see N94-14654 02-32)

Avail: CASI HC A03/MF A03

Virginia Tech has performed a comprehensive propagation experiment using the Olympus satellite beacons at 12.5, 19.77, and 29.66 GHz (which we refer to as 12, 20, and 30 GHz). Four receive terminals were designed and constructed, one terminal at each frequency plus a portable one with 20 and 30 GHz receivers for microscale and scintillation studies. Total power radiometers were included in each terminal in order to set the clear air reference level for each beacon and also to predict path attenuation. More details on the equipment and the experiment design are found elsewhere. Statistical results for one year of data collection were analyzed. In addition, the following studies were performed: a microdiversity experiment in which two closely spaced 20 GHz receivers were used; a comparison of total power and Dicke switched radiometer measurements, frequency scaling of scintillations, and adaptive power control algorithm development. Statistical results are reported. Author (revised)

RESULTS FROM A STUDY OF SCINTILLATION BEHAVIOR AT 12, 20, AND 30 GHz USING THE RESULTS FROM THE VIRGINIA TECH OLYMPUS RECEIVERS

Timothy Pratt and F. Haidara *In* JPL, Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 47-58 (For primary document see N94-14654 02-32)

Avail: CASI HC A03/MF A03

Tropospheric scintillations are rapid fluctuations of signal caused by multiple scattering from the small scale turbulent refractive index inhomogeneities in the troposphere. They can strongly impair satellite communications links operating at frequency above 10 GHz. The VA Tech OLYMPUS propagation experiment which includes 12, 20, and 30 GHz beacon receivers at an elevation angle of 14 degrees provides us with valuable multifrequency scintillation data. A long term analysis of tropospheric scintillation results from the VA Tech OLYMPUS experiment is presented. It includes statistics of both the scintillation intensity and the attenuation relative to clear air as well as seasonal, diurnal and meteorological trends. A comparison with the Consultative Committee for International Radio (CCIR) predictive model for scintillation fading is presented. Author (revised)

RADIOMETRIC OBSERVATIONS OF ATMOSPHERIC ATTENUATION AT 20.6 AND 31.65 GHz: THE WAVE PROPAGATION LABORATORY DATA BASE

Mark D. Jacobson, J. B. Snider, and E. R. Westwater *In* JPL, Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 61-79 (For primary document see N94-14654 02-32)

Avail: CASI HC A03/MF A03

The National Oceanic and Atmospheric Administration (NOAA) Wave Propagation Laboratory (WPL) presently operates five dual-channel microwave radiometers, one triple-channel microwave radiometer, and one six-channel microwave radiometer. The dual-channel radiometers operate at frequencies of 20.6 or 23.87 GHz and 31.4 or 31.65 GHz. The triple-channel radiometer operates at 20.6, 31.65, and 90.0 GHz. The six-channel radiometer operates at frequencies of 20.6, 31.65, 52.85, 53.85, 55.45, and 58.8 GHz. Recent brightness temperature measurements and attenuation values from some of the above radiometers are presented. These radiometric measurements, taken in different locations throughout the world, have given WPL a diverse set of measurements under a variety of atmospheric conditions. We propose to do a more complete attenuation analysis on these measurements in the future. In addition, a new spinning reflector was installed recently for the dual-channel radiometer at the Platteville, Colorado site. This reflector will extend our measurement capabilities during precipating conditions. Locating the three-channel and portable dual-channel radiometers at or near Greeley, Colorado to support the Advanced Communications Technology Satellite (ACTS) program is discussed. RAIN RATE DURATION STATISTICS DERIVED FROM THE MID-ATLANTIC COAST RAIN GAUGE NETWORK **c47**
Julius Goldhirsh *In* JPL, Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 93-103 (For primary document see N94-14654 02-32)
(Contract N00039-91-C-0001)
Avail: CASI HC A03/MF A03

A rain gauge network comprised of 10 tipping bucket rain gauges located in the Mid-Atlantic coast of the United States has been in continuous operation since June 1, 1986. Rain rate distributions and estimated slant path fade distributions at 20 GHz and 30 GHz covering the first five year period were derived from the gauge network measurements, and these results were described by Goldhirsh. In this effort, rain rate time duration statistics are presented. The rain duration statistics are of interest for better understanding the physical nature of precipitation and to present a data base which may be used by modelers to convert to slant path fade duration statistics. Such statistics are important for better assessing optimal coding procedures over defined bandwidths. Author (revised)

RAIN-RATE DATA BASE DEVELOPMENT AND RAIN-RATE CLIMATE ANALYSIS **c47**
Robert K. Crane *In* JPL, Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 105-128 (For primary document see N94-14654 02-32)
Avail: CASI HC A03/MF A03

The single-year rain-rate distribution data available within the archives of Consultative Committee for International Radio (CCIR) Study Group 5 were compiled into a data base for use in rain-rate climate modeling and for the preparation of predictions of attenuation statistics. The four year set of tip-time sequences provided by J. Goldhirsh for locations near Wallops Island were processed to compile monthly and annual distributions of rain rate and of event durations for intervals above and below preset thresholds. A four-year data set of tropical rain-rate tip-time sequences were acquired from the NASA TRMM program for 30 gauges near Darwin, Australia. They were also processed for inclusion in the CCIR data base and the expanded data base for monthly observations at the University of Oklahoma. The empirical rain-rate distributions (edfs) accepted for inclusion in the CCIR data base were used to estimate parameters for several rain-rate distribution models: the lognormal model, the Crane two-component model, and the three parameter model proposed by Moupfuma. The intent of this segment of the study is to obtain a limited set of parameters that can be mapped globally for use in rain attenuation predictions. If the form of the distribution can be established, then perhaps available climatological data can be used to estimate the parameters rather than requiring years of rain-rate observations to set the parameters. The two-component model provided the best fit to the Wallops Island data but the Moupfuma model provided the best fit to the Darwin data. Author (revised)

A DATABASE FOR PROPAGATION MODELS
Anil V. Kantak, Krisjani Suwitra, and Choung Le *In its* Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 129-141 (For primary document see N94-14654 02-32)
Avail: CASI HC A03/MF A03

The NASA Propagation Program supports academic research that models various propagation phenomena in the space research frequency bands. NASA supports such research via school and institutions prominent in the field. The products of such efforts are particularly useful for researchers in the field of propagation phenomena and telecommunications systems engineers. The systems engineer usually needs a few propagation parameter values for a system design. Published literature on the subject, such as the Cunsultative Committee for International Radio (CCIR) publications, may help somewhat, but often times, the parameter values given in such publications use a particular set of conditions which may not quite include the requirements of the system design. The systems engineer must resort to programming the propagation phenomena model of interest and to obtain the parameter values to be used in the project. Furthermore, the researcher in the propagation field must then program the propagation models either to substantiate the model or to generate a new model. The researcher or the systems engineer must either be a skillful computer programmer or hire a programmer, which of course increases the cost of the effort. An increase in cost due to the inevitable programming effort may seem particularly inappropriate if the data generated by the experiment is to be used to substantiate the already well-established models, or a slight variation thereof. To help researchers and the systems engineers, it was recommended by the participants of NASA Propagation Experimenters (NAPEX) 15 held in London, Ontario, Canada on 28-29 June 1991, that propagation software should be constructed which will contain models and prediction methods of most propagation phenomenon. Moreover, the software should be flexible enough for the user to make slight changes to the models without expending a substantial effort in programming.

RESULTS OF MULTIBAND (L, S, Ku BAND) PROPAGATION MEASUREMENTS AND MODEL FOR HIGH ELEVATION ANGLE LAND MOBILE SATELLITE CHANNEL
M. A. N. Parks, G. Butt, Barry G. Evans, and M. Richharia (International Maritime Satellite Organization, London, England.) *In* JPL, Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 193-202 (For primary document see N94-14654 02-32)
Avail: CASI HC A02/MF A03

Signal propagation in the land mobile satellite (LMS) service is an important consideration due to its critical impact on the overall economic and commercial viability of the system. At frequencies allocated for LMS systems, shadowing of the line-of-sight (LOS) signal as well as multipath propagation phenomena can severely impair the link availability. In particular, as most of the studies have shown, the shadowing of LOS signal causes long and deep fades in a variety of mobile environments due to the inherent nature of the channel between the satellite and a mobile. Roadside obstacles, such as buildings, trees, utility poles etc., in the immediate vicinity of a mobile and the surrounding terrain are major sources of signal shadowing in LMS links. Therefore, a proper knowledge of link degradation is essential for cost-effective planning of a satellite based mobile communication system. The results of a propagation campaign undertaken to characterize the fading nature of LMS channel at high elevation angles is presented. It was envisaged that one of the most important physical variables contributing to the amount of LOS signal shadowing is the elevation angle of the satellite. At higher elevation angles to the satellite, less obstructions in the direct satellite-to-mobile path would therefore amount to statistically better link availability. Narrowband channel measurements were carried out at three RF frequencies corresponding to L (1.3 GHz), S (2.32/2.45 GHz), and Ku (10.4 GHz) bands. The campaign itself was divided into two phases to observe the effects of seasonal variation of foliage on the roadside trees. Phase measurements were carried out in September 1991 and in April 1992. Some important aspects from the statistical analysis of the propagation data are presented.

Ionosphere scintillation can effect satellite telecommunication up to Ku-band. Nighttime scintillation can be attributed to large-scale inhomogeneity in the F-region of the ionosphere predominantly between heights of 200 and 600 km. Daytime scintillation has been attributed to sporadic E. It can be thought of as occurring in three belts: equatorial, high-latitude, and mid-latitude, in order of severity. Equatorial scintillation occurs between magnetic latitudes +/- 25 degrees, peaking near +/- 10 degrees. It commonly starts abruptly near 2000 local time and dies out shortly after midnight. There is a strong solar cycle dependence and a seasonal preference for the equinoxes, particularly the vernal one. Equatorial scintillation occurs more frequently on magnetically quiet than on magnetically disturbed days in most longitudes. At the peak of the sunspot cycle scintillation depths as great as 20 dB were observed at L-band.

TREE ATTENUATION AT 20 GHz: FOLIAGE EFFECTS
Wolfhard J. Vogel and Julius Goldhirsh (Johns Hopkins Univ., Laurel, MD.) *In* JPL, Proceedings of the Seventeenth NASA Propagation Experimenters Meeting (NAPEX 17) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Aug. 1993 p 219-223 (For primary document see N94-14654 02-32)
(Contracts JPL-956520; N00039-91-C-0001)
Avail: CASI HC A01/MF A03

Static tree attenuation measurements at 20 GHz (K-Band) on a 30 deg slant path through a mature Pecan tree with and without leaves showed median fades exceeding approximately 23 dB and 7 dB, respectively. The corresponding 1% probability fades were 43 dB and 25 dB. Previous 1.6 GHz (L-Band) measurements for the bare tree case showed fades larger than those at K-Band by 3.4 dB for the median and smaller by approximately 7 dB at the 1% probability. While the presence of foliage had only a small effect on fading at L-Band (approximately 1 dB additional for the median to 1% probability range), the attenuation increase was significant at K-Band, where it increased by about 17 dB over the same probability range.

Electrical noise in microwave field effect transistors (MESFET, HEMT and pseudomorphic HEMT) and in Heterojunction Bipolar Transistors (HBT) is investigated. The excess noise in the low frequency range which can limit or degrade the performance of nonlinear microwave circuits such as oscillators or mixers is described. The noise in the microwave range which takes a prominent place in the performance of linear microwave applications (amplifiers, active filters, etc.) is considered. A theoretical background on the excess noise sources in active microwave devices is given. Results of low fequency noise measurements versus frequency, geometrical features, bias and temperature performed on Field Effect Transistor (FET) and Heterojunction Bipolar Transistor (HBT) are presented. This study allowed the possible sources of excess noise to be understood and the corner noise frequency of these devices to be determined. Microwave noise on GaAs FET and HBT is also investigated. Noise measurements versus bias in GaAs FET confirmed the higher capabilities of pseudomorphic High Electron Mobility Transistor (HEMT) than HEMT for low noise amplification. Concerning the noise potentialities of HBT, a minimum figure smaller than 3 dB at 20 GHz on GaInP/GaAs structure was observed which is considered to be the lowest noise figure observed on bipolar devices at K band. A modular test model for isolated word recognition with restricted vocabulary is developed and an effective and compact parameter representation of speech signal is realized for extraction of robust speech features. Standard processes, mathematical methods and algorithms for speech recognition and coding, such as vector quantization, dynamic programming and time warping, hidden Markov models and Viterbi algorithm, are presented. An experimental system for speech signal preprocessing, which combines modules of mel-scale cepstral coefficients, trace segmentation and dynamic time normalization, is described. Implementation possibilities of neuronal networks were discussed with focus on multilayer perceptrons because of its learning capabilities. ESA

COVERAGE ASPECTS OF A SINGLE FREQUENCY NETWORK DESIGNED FOR DIGITAL AUDIO BROADCASTING
C. P. Bell and W. F. Williams 1993 14 p Original contains color illustrations
(BBC-RD-1993/3) Copyright Avail: Issuing Activity (BBC, Kingswood, England)

Since the early 1960s, the VHF/FM pilot tone system has been used by broadcasters to supply high quality stereophonic programs to listeners equipped with fixed receivers and modest gain directional antennas mounted externally at a height of about ten meters above ground levels. More recently, with the advent of improved radio receivers and digital technology in the reproduction industry, the broadcasters' target audience has changed and listeners now expect high fidelity reception, comparable to CD quality, on their portable and mobile receivers. In many areas, the demand for high quality can be supplied using the existing VHF/FM networks. There are, however, areas where good portable and mobile reception cannot be obtained, due to shadowing and multipath. This report discusses the coded orthogonal frequency division multiplex (COFDM) channel coding and modulation system developed within the Eureka 147 digital audio broadcasting (DAB) project, which is able to overcome the problems of multipath. Indeed, it can make use of multipath signals. This fact leads to the concept of a Single Frequency Network (SFN) where a single DAB COFDM frequency block can be used to supply five or six programs to a whole country. The derivation of minimum required field strength levels for DAB COFDM signals, and the allowances required for high percentage location coverage, necessary for digital systems, are presented together with a spectrum efficiency comparison between SFN and VHF/FM networks. Theoretical lattice planning, using the CCIR Rec. 370 prediction method, is used initially to illustrate the SFN concept and suggest required effective radiated powers. The results of SFN coverage studies for the UK, using existing broadcast transmitter sites and utilizing both the Rec. 370 and the BBC terrain data based prediction methods, are given. In addition, a possible four frequency block SFN plan for Europe is discussed. The Report concludes that, in comparison, networks using the Eureka 147 DAB system exhibit a

distinct spectrum and power advantage over conventional FM networks.

Calculating microwave opacity from a weakly absorbing gas mixture using a resonator requires measuring the quality factor of that resonator which necessitates accurately determining the center frequency (f(sub O)) and the half power bandwidth (Delta-f) of a noisy resonant line. The center frequency can be determined very accurately and varies very little over many measurements (a few kHz at GHz frequencies or a few hundredths of a percent). The greater source of error in estimating the Q of a resonator come from the bandwidth measurements. The half power bandwidth is determined essentially by eye-fitting a curve over a noisy resonant line and measuring with a spectrum analyzer. Author (revised)

A subband coding is designed with space-time frequency spectrum decomposition. Digitalized television signals and general discrete three dimensional signals are described and spectrum and spectral recurrences in space-time frequency area were calculated. A three dimensional subscanning with a time periodicity of four half images was carried out in motion controlled decomposition so that the time redundancy parts of a television signal are taken into account; varied possibilities of filtration were estimated with this scanning sampling and analyzed in terms of advantages and disadvantages for coding. Computerized simulations of very critical television and high definition television image sequences were carried out so that statistical parameters in subbands could be measured and the effectiveness of source coding processes was established with dependence on filter properties. An empirical method was chosen for subband coding and the influence of coding errors on the reconstructed image was examined with simulation. Perturbation spectrum was evaluated with frequency response of synthesis filter. A concept for data reduction of the components of high definition television signals such as luminance signal and two color difference signals is presented. It is established that three dimensional decomposition with motion controlled analysis and synthesis filtration allows higher reductions to be obtained than with purely spatial decomposition. ESA

The role of sulfur dioxide in lidar remote measurement of ozone is investigated. Measurements of tropospheric ozone with ultraviolet differential absorption lidar are found to be perturbed by sulfur dioxide unless lidar signal and reference wavelengths are chosen so that the differential SO2 absorption cross section is zero. Measurements of SO2 cross sections were performed between 265 and 298 nm with a resolution inferior to 3 micrometers, wavelengthh uncertainty lower than 4 picometers and cross section error lower than 3 percent. 13 pairs of wavelengths between 277.6 and 289.6 nm, with ozone cross section differences between 2 and 20 by 10 (exp -23)sq m, are proposed for which SO2 cross sections are minimum or equal. A remote measuring system, which is based on the principle of differential absorption and diffusion lidar, is developed for detection of nitrogen dioxide, sulfur dioxide, and ozone. The ARGOS (Advanced Remote Gaseous Oxides Sensor) system uses differential absorption of light with different wavelengths; for that two short light pulses from pumped dye lasers are simultaneously sent in the atmosphere. A three component Doppler sodar is used for measuring wind direction and velocity. The system allows atmosphere backscattering coefficient to be estimated as a measure for spray and dust concentration in the air. Curves of SO2 distribution in an industrial area and horizontal profile of ozone concentration are presented as examples. ESA

The transport equations for energy, momentum, orbital angular momentum and self-angular momentum of the electromagnetic wave packet propagating in the weakly absorbing homogeneous stationary anisotropic and gyrotropic medium with temporal and spacial dispersion have been obtained. These equations contain terms up to second order expansion in series for values lambda/L and Omega/omega (here lambda and omega are the wave length and wave frequency, L and i/Omega-the characteristic length and time of the wave amplitude change). It has been shown that the self-angular momentum (spin) conservation law is true only for transversal waves with circular polarization. Expressions for spin density, its flux, and power losses have been determined. DOE

(DE93-012856; SAND-93-1006C; CONF-9305186-1) Avail: CASI HC A01/MF A01

The successful design and testing of a three-phase planar integrated magnetic micromotor is presented. Fabrication is based on a modified deep X-ray lithography and electroplating or LIGA process. Maximum rotational speeds of 33,000 rpm are obtained in air with a rotor diameter of 285 microns and do not change when operated in vacuum. Real time rotor response is operated with an integrated shaft encoder. Long lifetime is evidenced by testing to over 5(10)(sup 7) rotation cycles without changes in performance. Projected speeds of the present motor configuration am in the vicinity of 100 krpm and are limited by torque ripple. Higher speeds, which are attractive for sensor applications. require constant torque characteristic excitation as is evidenced by ultracentrifuge and gyroscope design. Further understanding of electroplated magnetic material properties will drive these performance improvements. DOE

(NASA-CR-193727; NAS 1.26:193727) Avail: CASI HC A01/MF A01

This paper reports on the application of spatially variant infinite impulse response (IIR) filter banks to subband image coding. The new filter bank is based on computationally efficient recursive polyphase decompositions that dynamically change in response to the input signal. In the absence of quantization, reconstruction can be made exact. However, by proper choice of an adaptation scheme, we show that subband image coding based on time varying filter banks can yield improvement over the use of conventional filter banks. 1/f NOISE AND OXIDE TRAPS IN MOSFETs
D. M. Fleetwood, T. L. Meisenheimer, and J. H. Scofield (Oberlin Coll., OH.) 1993 8 p Presented at the 12th International Conference on Noise in Physical Systems and 1/f Fluctuations, Saint Louis, MO, 16-20 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-007581; SAND-93-0037C; CONF-930866-1) Avail: CASI HC A02/MF A01

MOSFET's historically have exhibited large 1/f noise magnitudes because of carrier-defect interactions that cause the number of channel carriers and their mobility to fluctuate. Uncertainty in the type and location of defects that lead to the observed noise have made it difficult to optimize MOSFET processing to reduce the level of 1/f noise. This has limited one's options when designing devices or circuits (high-precision analog electronics, preamplifiers, etc.) for low-noise applications at frequencies below (approximately)10-100 kHz. We have performed detailed comparisons of the low-frequency 1/f noise of MOSFET's manufactured with radiation-hardened and non-radiation-hardened processing. We find that the same techniques which reduce the amount of MOSFET radiation-induced oxide-trap charge can also proportionally reduce the magnitude of the low-frequency 1/f noise of both unirradiated and irradiated devices. MOSFET's built in radiation-hardened device technologies show noise levels up to a factor of 10 or more lower than standard commercial MOSFET's of comparable dimensions, and our quietest MOSFET's show noise magnitudes that approach the low noise levels of JFETS. Guidelines and rationale that will assist system developers in specifying consistent, necessary, and achievable chip-level testability requirements are provided. A bottom-up design procedure is recommended that emphasizes the importance of chip testability estimation and built-in-test evaluation during chip design to minimize system life-cycle cost. A comprehensive set of cost-related testability attributes was developed, which address test generation, test application, and fault isolation and repair. This set of attributes was then prioritized on the basis of usefulness and estimation cost. A set of chip-level design-for-testability and built-in-test techniques were selected from open literature sources. Preliminary analyses of eleven of the more promising techniques considered nine criteria in the areas of: impact on testability, cost, and applicability to standard design practices. Three of the techniques were subjected to in-depth analyses that included the results of case studies. The techniques considered in the in-depth studies were: Circular Built-In-Self-Test, LSSD On-Chip Self-Test (LOCST), and CrossCheck. DTIC

(DE93-013313; UCRL-ID-112587) Avail: CASI HC A03/MF A01

In 1989, two researchers published a design for an increased efficiency x-ray detector. The design increased the efficiency of a semiconductor detector by interspersing layers of high-z metal within it. Semiconductors such as silicon make good, high-resolution radiation detectors, but they have low efficiency because they are low-z materials ($z = 14$). High-z metals, on the other hand, are good absorbers of high-energy photons. By interspersing high-z metal layers with semiconductor layers, the researchers combined the high absorption efficiency of the high-z metals with the good detection capabilities of a semiconductor. This project is an attempt to use the same design to produce a high-efficiency, room temperature gamma ray detector. By their nature, gamma rays require thicker metal layers to efficiently absorb them. These thicker layers change the behavior of the detector by reducing the resolution, compared to a solid state detector, and shifting the photopeak by a predictable amount. During the last year, the authors have procured and tested a commercial device with operating characteristics similar to those of a single layer of the composite device. They have modeled the radiation transport in a multi-layered device, to verify the initial calculations of layer thickness and composition. They have modeled the electrostatic field in different device designs to locate and remove high-field regions that can cause device breakdown. They have fabricated 14 single layer prototypes. DOE

ANALYSIS AND CHARACTERIZATIONS OF PLANAR TRANSMISSION STRUCTURES AND COMPONENTS FOR SUPERCONDUCTING AND MONOLITHIC INTEGRATED CIRCUITS Final Technical Report, 1 Jan. - 31 Dec. 1991
Tatsuo Itoh 16 Mar. 1992 4 p
(Contract NCC3-192)
(NASA-CR-193675; NAS 1.26:193675) Avail: CASI HC A01/MF A01

The research effort was continued to design and characterize superconducting transmission line structures. The research during this period was concentrated on the implementation of a superconductor into coplanar waveguide structures. First, the superconducting coplanar waveguide was examined, and compared with a superconducting microstrip line in terms of loss characteristics and their design aspects. Then, the research was carried on the design and characterization of the coplanar waveguide family

in the packaging environment. The transition between the coaxial line to the conductor backed coplanar waveguide was also designed for the measurement of the superconducting conductor backed coplanar waveguide. Author (revised)

METAL OXIDE VARISTOR FEASIBILITY STUDY
L. M. Levinson and H. A. Comanzo 1993 34 p
(Contract W-7405-eng-36)
(DE93-012921; LA-SUB-93-168) Avail: CASI HC A03/MF A01

We have successfully fabricated varistor material meeting the initial voltage stabilization specifications for the Dual Axis Radiographic Hydratest (DARHT) facility. A time dependent voltage droop ('overshoot') has been identified as a potential issue and some promising avenues to reduce the overshoot are outlined. In particular, preliminary tests using series capacitance gives an overshoot of a few percent. These data, coupled with our previous experience on low-overshoot varistor formulations, lead to the conclusion that specially tailored varistor material might be suitable for the DARHT application. SOLDERABILITY OF SURFACE MOUNT DEVICES
Nanette S. Holder Jun. 1993 14 p
(AD-A265751; ARFSD-TR-93001) Avail: CASI HC A03/MF A01

As electronic products become much smaller, a limiting factor in the reduction of product size has been the size of the electronic components which make up the product. The leads of the current electronic components are inserted onto a printed circuit board through holes. Due to the use of wire leads, it becomes more difficult to decrease the size of the components. A new method was created to mount components directly to the surface of the printed circuit board. This new technique is surface mount technology. A concern over the use of this is experienced by the military. Since the leads are not inserted through the board and crimped before soldering as conventional components are mounted, there is some regard as to whether the components can be mounted securely to the board. Due to the high forces that many munitions experience when dispensed, it is imperative that the electronic components be soldered to the circuits boards so they will not slip out of place or fall from the board. The military also requires many munitions to lie dormant in storage warehouses for up to 20 years. When the munition is needed, it must perform reliably. Little work has been done to study the effects of this long-term storage on these surface mount devices, particularly on the ability of different soldering techniques used to attach surface mount components to printed circuit boards to withstand damaging effects of long-term storage. RIGID-FLEXIBLE PRINTED WIRING BOARDS
E. V. Sydow May 1993 52 p
(Contract DE-AC04-76DP-00613)
(DE93-013938; KCP-613-5043) Avail: CASI HC A04/MF A01

Rigid-flexible printed wiring board materials, fabrication processes, product requirements, and reliability were established. Considerable effort was spent testing plated-through holes, analyzing plated-through hole failure mechanisms, and then incorporating materials, processes, and product requirements to provide adequate control and reduce failures. The principal processes developed were tooling concepts, process sequence, lamination, drilling, plasma etchback, copper electroplating, and solder coating. Product requirements and reliability were established with thermal shock, thermal stress, innerlayer adhesion, and fold flexibility tests. Plated-through hole failure mechanisms were analyzed with thermal mechanical and finite element analyses. DOE

A MILLIMETER-WAVE TUNNELADDER TWT Final Report, Oct. 1982 - Jan. 1986
D. Wilson Oct. 1988 54 p
(Contract NAS3-23347; RTOP 506-61-42)
(NASA-CR-182183; NAS 1.26:182183) Avail: CASI HC A04/MF A01

A millimeter-wave traveling wave tube (TWT) was developed using a dispersive, high-impedance forward wave interaction structure based on a ladder, with non-space-harmonic interaction, for a tube with high gain per inch and high efficiency. The 'TunneLadder' interaction structure combines ladder properties modified to accommodate Pierce gun beam optics in a radially magnetized PM focusing structure. The development involved the fabrication of chemically milled, shaped ladders diffusion brazed to diamond cubes which are in turn active diffusion brazed to each ridge of a doubly ridged waveguide. Cold-test data, representing the (omega)(beta) and and impedance characteristics of the modified ladder circuit, were used in small and large-signal computer programs to predict TWT gain and efficiency. The structural design emphasizes ruggedness and reliability. Actual data from tested tubes verify the predicted performance while providing broader bandwidth than expected. Author (revised)

LOW-CURRENT TRAVELING WAVE TUBE FOR USE IN THE MICROWAVE POWER MODULE
Raymond W. Palmer, Peter Ramins, Dale A. Force, James A. Dayton, Ben T. Ebihara, and Robert P. Gruber Washington Jul. 1993 15 p
(RTOP 506-72-00)
(NASA-TP-3344; E-7329; NAS 1.60:3344) Avail: CASI HC A03/MF A01

The results of a traveling-wave-tube/multistage depressed-collector (TWT-MDC) design study in support of the Advanced Research Projects Agency/Department of Defense (ARPA/DOD) Microwave Power Module (MPM) Program are described. The study stressed the possible application of dynamic and other tapers to the RF output circuit of the MPM traveling wave tube as a means of increasing the RF and overall efficiencies and reducing the required beam current (perveance). The results indicate that a highly efficient, modified dynamic velocity taper (DVT) circuit can be designed for the broadband MPM application. The combination of reduced cathode current (lower perveance) and increased RF efficiency leads to (1) a substantially higher overall efficiency and reduction in the prime power to the MPM, and (2) substantially reduced levels of MDC and MPM heat dissipation, which simplify the cooling problems. However, the selected TWT circuit parameters need to be validated by cold test measurements on actual circuits. Author (revised)

HYMOSS SIGNAL PROCESSING FOR PUSHBROOM SPECTRAL IMAGING Final Technical Report
David E. Ludwig 11 Jun. 1991 91 p
(Contract NAS7-1065; SBIR-08.01-8211)
(NASA-CR-191341; NAS 1.26:191341; ISC158-ICN-FR/91-001) Avail: CASI HC A05/MF A01

The objective of the Pushbroom Spectral Imaging Program was to develop on-focal plane electronics which compensate for detector array non-uniformities. The approach taken was to implement a simple two point calibration algorithm on focal plane which allows for offset and linear gain correction. The key on focal plane features which made this technique feasible was the use of a high quality transimpedance amplifier (TIA) and an analog-to-digital converter for each detector channel. Gain compensation is accomplished by varying the feedback capacitance of the integrate and dump TIA. Offset correction is performed by storing offsets in a special on focal plane offset register and digitally subtracting the offsets from the readout data during the multiplexing operation. A custom integrated circuit was designed, fabricated, and tested on this program which proved that nonuniformity compensated, analog-to-digital converting circuits may be used to read out infrared detectors. Irvine Sensors Corporation (ISC) successfully demonstrated the following innovative on-focal-plane functions that allow for correction of detector non-uniformities. Most of the circuit functions demonstrated on this program are finding their way onto future IC's because of their impact on reduced downstream processing, increased focal plane performance, simplified focal plane control, reduced number of dewar connections, as well as the noise immunity of a digital interface dewar. The potential commercial applications for this integrated circuit are primarily in imaging systems. These imaging systems may be used for: security monitoring systems, manufacturing process monitoring, robotics, and for spectral imaging when used in analytical instrumentation. Author (revised)

SCREENING OF SOLAR CELLS
J. Appelbaum, A. Chait, and D. A. Thompson (Akron Univ., OH.) Jul.

1993 13 p
(Contract NCC3-104; RTOP 506-41-11)
(NASA-TM-106298; E-7987; NAS 1.15:106298) Avail: CASI HC A03/MF A01

Because solar cells in a production batch are not identical, screening is performed to obtain similar cells for aggregation into arrays. A common technique for screening is based on a single operating point of the I-V characteristic of the cell, usually the maximum power point. As a result, inferior cell matching may occur at the actual operating points. Screening solar cells based on the entire I-V characteristic will inherently result in more similar cells in the array. An array consisting of more similar cells is likely to have better overall characteristics and more predictable performance. Solar cell screening methods and cell ranking are discussed. The concept of a mean cell is defined as a cell 'best' representing all the cells in the production batch. The screening and ranking of all cells are performed with respect to the mean cell. The comparative results of different screening methods are illustrated on a batch of 50 silicon cells of the Space Station Freedom. Author (revised)

ADVANCED ELECTRIC MOTOR TECHNOLOGY FLUX MAPPING Final Report, 10 Apr. 1992 - 1993
George B. Doane, III, Warren Campbell, and Garvin Dean 8 Mar. 1993 158 p
(Contract NAS8-38609)
(NASA-CR-193824; NAS 1.26:193824; UAH-5-32903) Avail: CASI HC A08/MF A02

Design of electric motors which fulfill the needs of Thrust Vector Control (TVC) actuators used in large rocket propelled launch vehicles is covered. To accomplish this end the methodology of design is laid out in some detail. In addition a point design of a motor to fulfill the requirements of a certain actuator specified by MSFC is accomplished and reported upon. In the course of this design great stress has been placed on ridding the actuator of internally generated heat. To conduct the heat out of the motor use is made of the unique properties of the in house MSFC designed driving electronics. This property is that as along as they are operated in a quasi-linear mode the electronics nullify the effects of armature inductance as far as the phase of the armature current versus the rotor position is concerned. Actually the additional inductance due to the extended end turns in this design is of benefit because in the shorted armature failure mode the armature current in the fault (caused by the rotor flux sweeping past the armature) is diminished at a given rotor speed when compared to a more conventional motor with lower inductance. The magnetic circuit is analyzed using electromagnetic finite element methods. Author (revised)

A PHOTOVOLTAIC CATENARY-TENT ARRAY FOR THE MARTIAN SURFACE
M. Crutchik (Tel-Aviv Univ., Israel.), Anthony J. Colozza (Sverdrup Technology, Inc., Brook Park, OH.), and J. Appelbaum Aug. 1993 18 p
(Contract NAS3-25266; NAGw-2022; RTOP 506-41-11)
(NASA-TM-106306; E-8047; NAS 1.15:106306) Avail: CASI HC A03/MF A01

To provide electrical power during an exploration mission to Mars, a deployable tent-shaped structure with a flexible photovoltaic (PV) blanket is proposed. The array is designed with a self-deploying mechanism utilizing pressurized gas expansion. The structural design for the array uses a combination of cables, beams, and columns to support and deploy the PV blanket. Under the force of gravity a cable carrying a uniform load will take the shape of a catenary curve. A catenary-tent collector is self shadowing which must be taken into account in the solar radiation calculation. The shape and the area of the shadow on the array was calculated and used in the determination of the global radiation on the array. The PV blanket shape and structure dimension were optimized to achieve a configuration which maximizes the specific power (W/kg). The optimization was performed for four types of PV blankets (Si, GaAs/Ge, GaAs CLEFT, and amorphous Si) and four types of structure materials (Carbon composite, Aramid Fiber composite, Aluminum, and Magnesium). The results show that the catenary shape of the PV blanket, which produces the highest specific power, corresponds to zero end angle at the base with respect to the horizontal. The tent angle is determined by the combined effect of the array structure specific mass and the PV blanket output power. The combination of carbon composite structural material and GaAs CLEFT solar cells produce the highest specific power. The study was carried out for two sites on Mars corresponding to the Viking Lander locations. The designs were also compared for summer, winter, and yearly operation. Author (revised)

ON A NONMINIMAL GAUGE INTERACTION OF A SCALAR FIELD IN D=2+1 CHERN-SIMONS-MAXWELL THEORY
S. M. Latinskij and D. P. Sorokin 1991 6 p
(DE93-621380; KFTI-91-12) Avail: CASI HC A01/MF A01 (US Sales Only)

The consequences of spontaneous symmetry breaking are considered in a model, describing nonminimal gauge interaction of a scalar field (analogous to that of spin-1/2 particle with anomalous magnetic momentum). It is shown that the gauge field Chern-Simons term can be generated as a result of symmetry breaking if it was not initially present in the action and, at the same time, the Maxwell term can be canceled by symmetry breaking corrections. A very large scale integration (VLSI) circuit is assumed to contain a number of modules such as random logic circuits and read-only memories. By modifying the subcircuits locally, via selecting a design for testability (DFT) scheme, and monitoring the whole test globally the VLSI circuit is made testable. Following this framework, two problems are recognized: selection of the proper DFT technique to optimize the testability aspects of the macro cell, and modification of the macro cell to conform with the chosen DFT scheme. A generalized selection methodology has been developed to solve the selection problem employing an optimization technique and a satisfaction procedure to arrive at a solution that meets the user constraints. A knowledge based system that implements the selection mechanism has been developed to choose a built-in self-test (BIST) technique for random logic circuits. Modifying a circuit to comply with a given DFT scheme has also been studied for two DFT techniques and a number of tools have been developed. A new scan design methodology has been introduced which has simple design rules and employs two area efficient memory elements as internal storage. A comprehensive design tool has been developed to check circuits for design rule violations, check and correct scan design rule violations, and synthesize the scan path. Author (CISTI)

MMIC PACKAGING TECHNOLOGY DEVELOPMENT Final Technical Report, Nov. 1989 - Mar. 1993
K. Li and S. Yuan 15 Mar. 1993 62 p
(Contract NAS3-25864)
(NASA-CR-194183; NAS 1.26:194183; W-4G157) Avail: CASI HC A04/MF A01

Packaging technology for microwave and millimeter-wave monolithic integrated circuits (MMIC's) was developed. Two packaging approaches were investigated for RF performance and mechanical integrity. One is a packaging approach using quartz (fused silica) material and a glass sealing process. The other is a packaging approach using ceramic (92 percent Alumina) material and a co-firing process. Test results indicate both packaging approaches provide wide frequency band and low insertion loss. The quartz package-breadboard components exhibited operating frequency up to 35 GHz, with insertion loss less than 1.30 dB at 35 GHz. Quartz packages were designed and fabricated to investigate reproducibility. Findings from sample fabrication indicate that metallization and glass sealing process for quartz packages requires substantial improvement before reproducibility can be established. Ceramic packages were designed and

fabricated for proof-of-concept in support of MMIC packaging technology development. The ceramic packages exhibited operating frequency up to 36 GHz, with insertion loss less than 1.7 dB at 36 GHz. These proof-of-concept MMIC packages not only show low insertion loss and wide frequency band but also demonstrated the hermetic-seal capability and the mechanical strength for many MMIC applications. Current co-fired ceramic process permits cost effectiveness and timely insertion of MMIC's technology. Author (revised)

POWER CONVERTERS FOR THE 120 V BUS SUPPLY CONTROL [CONVERTISSEURS DE PUISSANCE POUR LA REGULATION DE BARRE D'ALIMENTATION 120 V]
Christian Elisabelar Mar. 1993 52 p In FRENCH
(CNES-NT-134; ETN-93-94411) Copyright Avail: CASI HC A04/MF A01

Power converters for the 120 V bus supply control in such projects as Columbus and Hermes are addressed. Because of the power levels involved and the existing state of the art, several converter modules need to be connected in parallel to supply a single bus. To simplify the study, the power of each converter is set at around 1 kW. Many converter structures which satisfy requirement specifications and several solutions, with or without galvanic insulation, are proposed. The choice and sizing of the converter structure are considered. Stress factors and available technology are selection criteria in determining the most suitable structures. The dimensions of each structure, taking into account the rules of space design enable efficiency to be analytically estimated and it is subsequently verified experimentally. The converter command and its functional performance are then addressed. Numerical simulations with SUCCESS software are run to observe the actual operation of the power part of the converter and to develop the command law with its regulation parameters. The converter is simulated in its entirety and different transients are studied like load variation, no load operating point, short circuit. The response time, stability and behavior under disturbed conditions are thus known. A comparison of the various structures studied enabled the optimal converter to be chosen for some 120 V regulated bus applications. ESA

FIELD EMITTER ARRAY RF AMPLIFIER DEVELOPMENT PROJECT. PHASE 1: CATHODE TECHNOLOGY DEVELOPMENT Quarterly Progress Report No. 6, 1 Jan. - 31 Mar. 1993
Bertram Hui 31 May 1993 39 p
(Contract MDA972-91-C-0028)
(AD-A266346) Avail: CASI HC A03/MF A01

Process in research and development continues at all sites. MCNC's program continues at full speed with smooth transition of project personnel. Electrical testing of field emitter arrays fabricated at MCNC continues at all sites. Effects of anode proximity on emission current capture are being investigated. Two new processes for gate opening alignment are under development. Both eliminate the necessity of retaining the nitride caps on the field emitter tips through the entire processing sequence. One requires alignment during an additional photolithography step, the other is self-aligning. Refinements in processing continue. Better control of the anisotropic silicon etch for tip formation has been achieved. In-house chem-mechanical polishing is still under investigation as a method for wafer planarization. Other materials are being evaluated for use as the insulating layer between substrate and gate. Better methods for depositing evaporated oxides are being sought, and the oxides as deposited are being characterized. Vacuum bonder and test system is operational. The bonding chamber has been outfitted for DC testing to improve test throughput, with electrical feedthroughs rated for 700 V at 10 A. Failure analysis of field emitter arrays from two lots was completed. Five mechanisms in two classes were identified as contributors to device failures: those mechanisms that destroyed working emitters, and those that prevented emitters from working. In anticipation of continued ARPA funding for the field emitter amplifier project, revised budgetary and scheduling information was prepared. Design of the process and reticle set for the next generation of devices has already begun. DTIC

OPERATION OF HIGH POWER CONVERTERS IN PARALLEL Final Report
D. K. Decker and L. Y. Inouye Mar. 1993 7 p
(Contract NAS3-25093; RTOP 474-42-10)
(NASA-CR-191096; E-7685; NAS 1.26:191096) Avail: CASI HC A02/MF A01

High power converters that are used in space power subsystems are limited in power handling capability due to component and thermal limitations. For applications, such as Space Station Freedom, where multi-kilowatts of power must be delivered to user loads, parallel operation of converters becomes an attractive option when considering overall power subsystem topologies. TRW developed three different unequal power sharing approaches for parallel operation of converters. These approaches, known as droop, master-slave, and proportional adjustment, are discussed and test results are presented. Author (revised)

A new simulator is developed to simulate the execution of an algorithm graph in accordance with the Algorithm to Architecture Mapping Model (ATAMM) rules. ATAMM is a Petri Net model which describes the periodic execution of large-grained, data-independent dataflow graphs and which provides predictable steady state time-optimized performance. This simulator extends the ATAMM simulation capability from a heterogenous set of resources, or functional units, to a more general heterogenous architecture. Simulation test cases show that the simulator accurately executes the ATAMM rules for both a heterogenous architecture and a homogenous architecture, which is the special case for only one processor type. The simulator forms one tool in an ATAMM Integrated Environment which contains other tools for graph entry, graph modification for performance optimization, and playback of simulations for analysis. COMMUNICATIONS AND CONTROL FOR ELECTRIC POWER SYSTEMS Report, 1990
H. Kirkham, A. Goettsche, D. Niebur, H. Friend, and A. Johnston 15 Jan. 1991 105 p
(Contract NAS7-918)
(NASA-CR-194503; JPL-Publ-91-44; NAS 1.26:194503) Avail: CASI HC A06/MF A02

The first section of the report describes the AbNET system, a hardware and software communications system designed for distribution automation (it can also find application in substation monitoring and control). The topology of the power system fixes the topology of the communications network, which can therefore be expected to include a larger number of

branch points, tap points, and interconnections. These features make this communications network unlike any other. The network operating software has to solve the problem of communicating to all the nodes of a very complex network in as reliable a way as possible even if the network is damaged, and it has to do so with minimum transmission delays and at minimum cost. The design of the operating protocols is described within the framework of the seven-layer Open System Interconnection hierarchy of the International Standards Organization. Section 2 of the report describes the development and testing of a high voltage sensor based on an electro-optic polymer. The theory of operation is reviewed. Bulk fabrication of the polymer is discussed, as well as results of testing of the electro-optic coefficient of the material. Fabrication of a complete prototype sensor suitable for use in the range 1-20 kV is described. The electro-optic polymer is shown to be an important material for fiber optic sensing applications. Appendix A is theoretical support for this work. The third section of the report presents the application of an artificial neural network, Kohonen's self-organizing feature map, for the classification of power system states. This classifier maps vectors of an N-dimensional space to a 2-dimensional neural net in a nonlinear way preserving the topological order of the input vectors. These mappings are studied using a nonlinear power system model. Author (revised)

SINGLE EVENT UPSET (SEU) TESTING OF SEMICONDUCTOR COMPONENTS AT THE MCMASTER ACCELERATOR LABORATORY
J. A. Davies, F. J. D. Almeida, D. Comedi, and J. W. Stark Mar. 1991 32 p
(DSIS-93-00071; CTN-93-60775) Avail: CASI HC A03

Single event upsets (SEU) occur when a single ionizing particle such as a cosmic ray passes through a microelectronic device, causing a random change in the logic state of a bistable circuit. The SEU phenomenon is of great interest since it is a source of errors and failures, notably on spaceborne microelectronic chips. A Van de Graaff accelerator was used to simulate the cosmic ray heavy ion linear energy transfer (LET) distribution found in earth orbit, and accelerator experiments were conducted in a dedicated facility for SEU testing of microelectronic devices. The first set of experiments set out to compare data obtained by two different SEU memory tester systems, and a second set attempted to compare data obtained using ions of different species and energy but the same LET, and to determine the accuracy of the concept of a constant SEU cross-section for a given LET. Observation of a fluence dependent SEU cross section and transient behavior led to a third set of experiments, designed to allow observation in more detail of the dynamics of these newly observed phenomena. The charge collection efficiency of detectors to high LET ions was also measured. CISTI

Electrochemical noise is interpreted as the occurrence of microscopic fluctuations of the potential of an electrochemical cell. A study was conducted on a number of commercial lithium cells to evaluate the practicality of electrochemical noise measurement as a diagnostic tool for performance and/or safety. The survey was limited to the following lithium based systems: sulfur dioxide, thionyl chloride, and manganese dioxide. The cells were subjected to a program of storage, environmental, and discharge conditions and then examined to determine whether there was any detectable effect on the electrochemical noise characteristics. While the study was of limited scope, it was nevertheless established that all cells exhibited some measurable electrochemical noise under certain conditions. The characteristics of the noise and its magnitude were influenced by many factors. The occurrence of observable noise above the instrumental background was generally associated with cells which had been discharged to between 80 and 100 percent of their nominal capacity. Most of the noise of interest was found at frequencies below 100 Hz. Author (CISTI)

PHASE ALIGNER FOR THE ELECTRONICALLY SCANNED THINNED ARRAY RADIOMETER (ESTAR) INSTRUMENT
William A. Chren, Jr. and Brian G. Zomberg Washington Sep. 1993 16 p
(NASA-TM-4518; Rept-93E02368; NAS 1.15:4518) Avail: CASI HC A03/MF A01

A prototype Phase Aligner (PA) or the Electronically Scanned Thinned Array Radiometer instrument has been designed and tested. Implemented in a single Xilinx XC3042PC84-125 Field Programmable Gate Array (FPGA), it is a dual-port register file which allows independent storage and phase coherent retrieval of antenna array data by the Central Processing Unit (CPU). It has dimensions of 4 x 20 bits and can be used at clock frequencies as high as 25 MHz. The ESTAR is a passive synthetic-aperture radiometer designed to sense soil moisture and ocean salinity at L-band. Author

DEVELOPMENT OF UHF SPARK-SWITCHED L-C OSCILLATORS
L. F. Rinehart, J. F. Aurand, J. M. Lundstrom, C. A. Frost, M. T. Buttram, P. E. Patterson, and W. R. Crowe 1993 4 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-015019; SAND-93-1280C; CONF-930616-2) Avail: CASI HC A01/MF A01

Spark switched L-C Oscillator (LCO) transmitters have operated in the Low, Medium, and High Frequency Bands (10's of kHz to 10's of MHz) throughout the history of radio. In the 1970's they were pushed into the VHF Band by Moran, et al. By applying ultra-fast gas switching techniques and by overcoming spark gap losses, the authors have operated LCO transmitters in the UHF (300 MHz to 3 GHz) region. Repetition rates greater than 1 kHz with peak voltages greater than 100 kV have been achieved. UHF oscillators are inherently small because of the low inductance and capacitance required to generate ultra-high frequencies. This size constraint forces the device to operate at very high voltage in order to store enough energy to drive the antenna in spite of series switch losses and parallel corona and stray capacity losses. The spark gap must close in a time short compared to one half an R-F cycle for efficient switching; this equates to a few hundred picoseconds at UHF. The LCO output is a damped sinusoid of a few cycles duration. While the fractional bandwidth (3-dB bandwidth divided by the center frequency) can be 10% to 80% depending on the Q, it is much smaller than the bandwidth of UWB impulse sources (100% bandwidth with multioctave coverage). Compared to UWB, the narrower bandwidth permits the use of higher gain antennas which can efficiently increase the effective radiated power (ERP) over a given frequency range. The authors have constructed L-C Oscillators with center frequencies of 450 MHz up to 800 MHz. The Q of these oscillators varies from 6 to 8 for the 450 MHz device, down to 1 to 2 for the 800 MHz unit. Q is increased when a resonant antenna or antenna-reflector combination is added. Prototypes with simple fat-dipole antennas and small parabolic reflectors (8 inches x 20 inches) have radiated normalized electric field strengths of 30 kV/m at 1 meter (measured in far-field and extrapolated back to 1 meter). THE DE HAAS-VAN ALPHEN STUDIES AND FERMI SURFACE PROPERTIES OF ORGANIC SUPERCONDUCTORS (ET)2X
J. Wosnitza (Karlsruhe Univ., Germany.), G. W. Crabtree, J. M. Williams, H. H. Wang, K. D. Carlson, and U. Geiser Apr. 1993 5 p Presented at the 1992 International Conference on Science and Technology of Synthetic Metals (ICSM), Goeteborg, Sweden, 12-18 Aug. 1992

(Contract W-31-109-eng-38)
(DE93-015157; ANL/MSD/CP-79640; CONF-9208132-13) Avail: CASI HC A01/MF A01

The de Haas-van Alphen (dHvA) measurements of organic superconductors (ET)2X, where ET stands for bis(ethylene) dithiotetrathiafulvalene (or BEDT-TTF) and X = IBr2, (NH4)Hg(SCN4) and Cu(NCS2) are reported. The strong two-dimensionality of the Fermi surface (FS) is clearly seen by the perfect 1/cos((Theta))-behavior of the dHvA frequency. The distinctive kind of beating and the angular dependence of the dHvA signal in (beta)-(ET)2IBr2 gives clear evidence for a lightly corrugated structure of the FS. Due to the nearly cylinder-shape of the FS the bare band structure effective mass, m(sub b), also shows a 1/cos((Theta))-dependence which is responsible for spin splitting zeros at certain angles. At these points, where the fundamental amplitude of the dHvA signal is vanishing, m(sub b) could exactly be determined and by comparison with the independently measured cyclotron effective mass the electron-phonon coupling constant could be estimated. ALTERNATE CLEANING METHODS FOR LCCAS Final Report
B. E. Adams Apr. 1993 36 p
(Contract DE-AC04-76DP-00613)
(KCP-613-5045) Avail: CASI HC A03/MF A01

The purpose of this project was to evaluate DI water followed by isopropyl alcohol (IPA) cleaning and no cleaning of leadless chip carriers (LCCs). Both environmentally safe methods were to be tested against the current chlorofluorocarbon (CFC) material cleaning baseline. Several experiments were run to compare production and electrical yields of LCCs cleaned by all three methods. The critical process steps most affected by cleaning were wire bonding, sealing, particle induced noise detection (PIND), moisture content, and electrical. Yields for the experimental lots cleaned by CFC, DI water plus IPA, and no cleaning were 56, 72, and 75 percent, respectively. The overall results indicated that vapor degreasing/ultrasonic cleaning in CFCs could be replaced by the aqueous method. No cleaning could also be considered if an effective dry method of particle removal could be developed. Author (revised)

COMMUNICATIONS AND CONTROL FOR ELECTRIC POWER SYSTEMS: POWER FLOW CLASSIFICATION FOR STATIC SECURITY ASSESSMENT
D. Niebur and A. Germond Feb. 1993 25 p
(Contract NAS7-918)
(NASA-CR-194512; JPL-Publ-93-6; NAS 1.26:194512) Avail: CASI HC A03/MF A01

This report investigates the classification of power system states using an artificial neural network model, Kohonen's self-organizing feature map. The ultimate goal of this classification is to assess power system static security in real-time. Kohonen's self-organizing feature map is an unsupervised neural network which maps N-dimensional input vectors to an array of M neurons. After learning, the synaptic weight vectors exhibit a topological organization which represents the relationship between the vectors of the training set. This learning is unsupervised, which means that the number and size of the classes are not specified beforehand. In the application developed in this report, the input vectors used as the training set are generated by off-line load-flow simulations. The learning algorithm and the results of the organization are discussed. Author (revised)

A method to verify the intermateability of connectors which have different origins and common specifications is provided. These connectors are designed for space applications and are known as Sub D connectors. These Sub D connectors investigated are specified under the American military standard MIL-C 24308. The evaluation of the connectors was carried out under three steps involving dimensional control, technological analysis, and a validation phase. The purpose of the dimensional control was to check the physical functionality of coupling these two different connectors. The technological analysis aimed at stressing and understanding possible performance differences between both connectors. The validation consisted of tests to evaluate the performance of two coupled connectors. ESA

MUTUAL INDUCTANCE BETWEEN PARTIALLY WOUND TORI AND A BIFILAR CONDUCTOR Ph.D. Thesis [GEGENINDUKTIVATAET ZWISCHEN TEILWEISE BEWICKELTEM RINGKERN UND EINER DOPPELLEITUNG]
Kanaga Sabapathy Mylvaganam 1992 126 p In GERMAN
(ETN-93-94388) Avail: CASI HC A07/MF A02

The solution of the three dimensional magnetostatic problem in cylindrical and toroidal coordinates is used to develop analytic expressions for the mutual inductance between bifilar current carrying conductors and partially wound tori of rectangular and circular cross sections. The double series containing associated Legendre functions obtained for the mutual inductance in the case of toroid with circular cross section was evaluated for certain dimensions of the toroid, after introducing a gemetrical factor dependent only on the dimensions of the toroid. To solve Laplace equations using only cylindrical coordinates, the rectangular toroid was viewed as one element of an infinite number of tori located symmetrically to the axis rotation and placed parallel to the flat surfaces of the original toroid. The mutual inductance in the case of the toroid with the rectangular cross-section was calculated using matrix formulation of the solution to the potential problem and the double series obtained for the mutual inductance was evaluated for the rectangular toroid dimensioned in such a way that both types of tori have the same average diameter and cross sectional area. To check the results from the two boundary value problems involving circular and rectangular tori, various special configurations of the rectangular toroid in the field of the bifilar lines were studied. The first configuration was that of an infinitely long toroid, on the surface of which the magnetic field was calculated and compared with the values obtained from the general solution. For two tori with almost equal cross sections the induced voltages in the windings were measured and calculated, whereby the results are found totally well within the experimental errors. For rough estimation of the induced voltage, some approximate expressions were given and numerically and experimentally verified. ESA

Argonne National Laboratory's Analysis & Diagnostic Laboratory (ADL) tests advanced batteries under simulated electric and hybrid vehicle operating conditions. The ADL facilities also include a post-test analysis laboratory to determine, in a protected atmosphere if needed, component compositional changes and failure mechanisms. The ADL provides a common basis for battery performance characterization and life evaluations with unbiased application of tests and analyses. The battery evaluations and post-test examinations help identify factors that limit system performance and life

and the most-promising R&D approaches for overcoming these limitations. Since 1991, performance characterizations and/or life evaluations have been conducted on eight battery technologies: Na/S, Li/S, Zn/Br, Ni/MH, Ni/Zn, Ni/Cd, Ni/Fe, and lead-acid. These evaluations were performed for the Department of Energy's. Office of Transportation Technologies, Electric and Hybrid Propulsion Division (DOE/OTT/EHP), and Electric Power Research Institute (EPRI) Transportation Program. The results obtained are discussed. MULTI-OUTPUT FLYBACK CONVERTER WITH ULTRAFAST CURRENT PROTECTION [CONVERTISSEUR FLYBACK A SORTIES MULTIPLES AVEC PROTECTION DE COURANT ULTRA RAPIDE]
Alphonse Barnaba Nov. 1992 21 p In FRENCH
(CNES-NT-133; ETN-93-93980) Copyright Avail: CASI HC A03/MF A01

The static regulations of a flyback converter with mono- and multioutputs are studied. The implementation of ultra far current protection and the analysis of the mutual inductance decoupling between outputs are discussed. Three breadboard model converters were investigated: a 'heavy' mode flyback converter, a 'light' mode flyback converter, and a miniwatt flyback converter. The experiments with the 'heavy' and 'light' breadboard models were performed with their own servomechanisms. An efficiency greater than 80% with an output less than 1 W was obtained for the miniwatt model converter. Such converters are often used for tensions inferior to 50 W. ESA

(Grant NAG1-1301)
(NASA-CR-194163; NAS 1.26:194163) Avail: CASI HC A09/MF A03

The processing and screen printing of the superconducting BSCCO and 123 YBCO materials on substrates is described. The resulting superconducting properties and the use of these materials as possible electrode materials for ferroelectrics at 77 K are evaluated. Also, work performed in the development of solid-state electromechanical actuators is reported. Specific details include the fabrication and processing of high strain PBZT and PLZT electrostrictive materials, the development of PSZT and PMN-based ceramics, and the testing and evaluation of these electrostrictive materials. Finally, the results of studies on a new processing technology for preparing piezoelectric and electrostrictive ceramic materials are summarized. The process involves a high temperature chemical reduction which leads to an internal pre-stressing of the oxide wafer. These reduced and internally biased oxide wafers (RAINBOW) can produce bending-mode actuator devices which possess a factor of ten more displacement and load bearing capacity than present-day benders. Viable high density packaging is of critical importance for future military systems, particularly space borne systems which require minimum weight and size and high mechanical integrity. A leading, emerging technology for high density packaging is multi-chip modules (MCM). During the 1980's, a number of different MCM technologies have emerged. In support of Strategic Defense Initiative Organization (SDIO) programs, Lawrence Livermore National Laboratory (LLNL) has developed, utilized, and evaluated several different MCM technologies. Prior LLNL efforts include modules developed in 1986, using hybrid wafer scale packaging, which are still operational in an Air Force satellite mission. More recent efforts have included very high density cache memory modules, developed using laser pantography. As part of the demonstration effort, LLNL and Phillips Laboratory began collaborating in 1990 in the Phase 3 Multi-Chip Module (MCM) technology demonstration project. The goal of this program was to demonstrate the feasibility of General Electric's (GE) High Density Interconnect (HDI) MCM technology. The design chosen for this demonstration was the processor core for a MIPS R3000 based reduced instruction set computer (RISC), which has been described previously. It consists of the R3000 microprocessor, R3010 floating point coprocessor and 128 Kbytes of cache memory. DOE

EARLY DETECTION OF INSULATION FAILURE IN ELECTRIC MOTORS Report of Investigations, 1993
G. T. Homce 1993 26 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-198208; BU-RI-9450) Avail: CASI HC A03

A system capable of monitoring mine electrical power systems and detecting impending component failure could significantly improve power system safety and reduce unscheduled equipment downtime. Such monitoring would require a method of evaluating electrical parameters, calculated from terminal values, for indications of component deterioration. The U.S. Bureau of Mines has targeted electrical failure of squirrel cage induction motors and examined the use of mathematical models to aid in the evaluation. The initial stage of the work is complete and has produced polynomial networks called adaptive learning networks (ALN's) that can detect and quantify winding insulation leakage simulated on laboratory motors. In the modeling process, empirical data from laboratory motors were used to select the electrical parameters most significant for assessing motor conditions, and mathematical expressions relating these parameters to simulated deterioration were formed. A HIGH VOLTAGE DIELECTRICALLY ISOLATED SMART POWER TECHNOLOGY BASED ON SILICON DIRECT BONDING Ph.D. Thesis - Inst. National des Sciences Appliquees, Toulouse [FILIERE TECHNOLOGIQUE DE PUISSANCE INTELLIGENTE HAUTE TENSION A ISOLATION DIELECTRIQUE BASEE SUR LA SOUDURE DIRECTE SUR SILICIUM]
Veronique Macary 1992 183 p In FRENCH Sponsored in part by Ministere de la Recherche et de la Technologie, Paris, France
(LAAS-92492; ETN-93-94360) Avail: CASI HC A09/MF A02

The feasibility of a dielectrically isolated technology based on the silicon direct bonding technique, for high voltage smart power applications in the 1000 to 1550 V/1 to 20 A range, where a vertical power switch is necessary, is investigated and demonstrated. Static and dynamic isolation of the low voltage circuitry integrated beside the vertical power transistor is the main concern of this family of circuits. The dielectric isolation offers better protection to the low voltage part than does the junction isolation, because of the elimination of the parasitic bipolar transistor inherent to the latter isolation technique. Silicon direct bonding provides a cost effective way to obtain a buried oxide isolation layer. In addition, the application requires a Si/Si bonded area in the active region of the vertical power switch. Strong influence of the prebonding cleaning in the electrical characteristics of the Si/Si interface is pointed out, and presence of crystalline defects is assumed to be at the origin of electrical failures. The main problems of silicon direct bonding process compatibility with standard processes were overcome, and a complete process flow, including the simultaneous integration of a vertical power bipolar transistor together with a bipolar control circuitry, was validated. Using a peripheral biased ring is shown to provide an easy way to optimize high voltage termination for the smart power circuit, while adding a non-additional technological step. This technique was studied by dimensional electrical simulations (BIDIM2 software), as well as analytically computed. ESA

DESIGN AND OPTIMIZATION OF HIGH VOLTAGE LATERAL DMOS DEVICES USING RESURF TECHNOLOGY Ph.D. Thesis - Toulouse Univ. [CONCEPTION ET OPTIMISATION DES COMPOSANTS DMOS LATERAUX HAUTE TENSION EN TECHNOLOGIE RESURF]
Mohamed El Amine Bouanane 1992 161 p In FRENCH
(LAAS-92511; ETN-93-94361) Avail: CASI HC A08/MF A02

One of the most promising solutions of the fabrication of switches for high voltage integrated circuits, Metal Oxide Semiconductor, the Lateral Double diffused Metal Oxide Semiconductor transistor (LDMOS) using the RESURF technique is discussed. This device is compatible with the low voltage circuits (CMOS or bipolar or BiCMOS); furthermore the LDMOS RESURF is easy to process, shows a high voltage handling capability and a good isolation. However, two major problems arise when optimizing this device: high on resistance value, and severe sensitivity of the breakdown voltage on technological parameters. To bypass these drawbacks the use of the following is used: shallow implantation to increase the concentration of the drift area between the channel and the drain; semiresistive layer, like SIPOS, deposited on the oxide between the gate and the drain. Numerical analysis shows that the use of both surface doping and the SIPOS technique will greatly improve the on resistance (between 40 and 60 of the On resistance value of the classic LDMOS RESURF). Moreover, an optimum breakdown voltage value can be reached for geometrical and physical parameters compatible with real technological tolerances. Geometrical parameters (channel drain distance, epi thickness and oxide thickness) and physical ones (epi doping, concentration and junction depth of surface doping) are optimized to obtain a breakdown voltage around 400 V. For the validation purpose of these rules, diodes and RESURF transistors using a surface doping technique and a SIPOS layer are fabricated. ESA

Progress in the scientific and technical activities in the following areas are described: time, frequency and electromagnetic metrology; electrical metrology; photometry; acoustics; materials; electromechanics; systems engineering; research carried out by the study center for television. The main scientific areas covered concern: metrology, regarding time and frequency; electromagnetic, photometric and acoustic quantities, with research carried out in primary measurement standards and the determination of fundamental physical constants; matter physics with the study of magnetic materials, amorphous thin film semiconductors and high critical temperature superconductors, and with the evaluation of magnetic, electrical, radiometric, photometric and acoustic properties of materials for specific applications; electrical equipment, with researchers and experimental activity aiming at improving characteristics, reliability and safety of electrical devices and plants; and techniques for information processing, with the development of techniques for image understanding and researchers on reliability of complex systems. A description of the calibration service in Italy is also given. ESA

ELECTROCHEMICAL PLANARIZATION FOR MICROELECTRONIC CIRCUITS
R. J. Contolini, S. T. Mayer, and A. F. Bernhardt 25 Mar. 1993 4 p Presented at the National Center for Advanced Information Components Manufacturing (NCAICM) Workshop, Albuquerque, NM, 30-31 Mar. 1993
(Contract W-7405-eng-48)
(DE93-017214; UCRL-JC-113618; CONF-9303198-1) Avail: CASI HC A01/MF A01

The need for flatter and smoother surfaces (planarization) in microelectronic circuits increases as the number of metal levels in ultra large scale integrated (ULSI) circuits increases. At Lawrence Livermore National Laboratory, the authors have developed an electrochemical planarization process that fills vias and trenches with metal (without voids) and subsequently planarizes the surface. Use is made of plasma-enhanced chemical vapor deposition (PECVD) of SiO2 for the dielectric layers and electroplated copper for the metalization. This report describes the advantages of this process over existing techniques, possibilities for collaboration, and previous technology transfer. DOE

In power supply systems, a need arises for wide-band loading currents monitors with a not galvanic contact from a control circuit. The measuring device is a reaction self-regulation circuit with a compensation of the value of the measured parameter. The measuring device may find extensive application in measurements of supply currents magnets and accelerator lenses. DOE

A COMPUTER MODEL FOR LIQUID JET ATOMIZATION IN ROCKET THRUST CHAMBERS Final Report, 22 May 1989 - 21 Nov. 1991
M. G. Giridharan, J. G. Lee, A. Krishnan, H. Q. Yang, E. Ibrahim, S. Chuech, and A. J. Przekwas 31 Dec. 1991 143 p Original contains color illustrations
(Contract NAS8-38425; SBIR-11.04-6576C)
(NASA-CR-194194; NAS 1.26:194194; CFDRC-4041/1) Avail: CASI HC A07/MF A02; 5 functional color pages

The process of atomization has been used as an efficient means of burning liquid fuels in rocket engines, gas turbine engines, internal combustion engines, and industrial furnaces. Despite its widespread application, this complex hydrodynamic phenomenon has not been well understood, and predictive models for this process are still in their infancy. The difficulty in simulating the atomization process arises from the relatively large number of parameters that influence it, including the details of the injector geometry, liquid and gas turbulence, and the operating conditions. In this study, numerical models are developed from first principles, to quantify factors influencing atomization. For example, the surface wave dynamics theory is used for modeling the primary atomization and the droplet energy conservation principle is applied for modeling the secondary atomization. The use of empirical correlations has been minimized by shifting the analyses to fundamental levels. During applications of these models, parametric studies are performed to understand and correlate the influence of relevant parameters on the atomization process. The predictions of these models are compared with existing experimental data. The main tasks of this study were the following: development of a primary atomization model; development of a secondary atomization model; development of a

model for impinging jets; development of a model for swirling jets; and coupling of the primary atomization model with a CFD code.

HIGH-FLUX TESTING OF HEAT PIPES FOR POINT-FOCUS SOLAR COLLECTOR SYSTEMS

D. R. Adkins 1993 7 p Presented at the National Conference and Exposition on Heat Transfer, Atlanta, GA, 8-11 Aug. 1993 -11 Aug. 1993

(Contract DE-AC04-76DP-00789)

(DE93-011581; SAND-92-2346C; CONF-930830-13) Avail: CASI HC A02/MF A01

The Department of Energy is currently funding the development of a power conversion system that uses a parabolic-dish collector to direct solar energy onto a 25-kWe Stirling engine/generator system. As part of this program, heat-pipe solar receivers are being developed to transfer 65 kW of thermal energy from the focus of the concentrator to the heater-tubes of the engine. These receivers operate at temperatures up to 800 C and with peak flux loads approaching 100 W/cm(sup 2). Designing a wick structure that can withstand these operating conditions has been a major part of the heat-pipe receiver development activities. Recently, bench-scale tests were performed on two advanced artery structures that are candidates for full-scale receivers. The arteries were able to lift sodium over 40 cm to cool a 30-cm(sup 2) patch on the bench-scale receiver's surface. Peak flux levels of approximately 80 W/cm(sup 2) were applied to the receiver surface. DOE

MODULATIONAL STABILITY OF PERIODIC SOLUTIONS OF THE KURAMOTO-SIVASKINSKY EQUATION Final Report

Demetrios T. Papageorgiou, George C. Papanicolaou (New York Univ., New York.), and Yiorgos S. Smyrlis (Manchester Univ., England.) Washington Jul. 1993 31 p Submitted for publication

(Contracts NAS1-19480; NAS1-18605; F49620-92-J-0023; NSF DMS-90-03227; NATO-CRG-920097; RTOP 505-90-52-01)

(NASA-CR-191502; NAS 1.26:191502; ICASE-93-44) Avail: CASI HC A03/MF A01

We study the long-wave, modulational, stability of steady periodic solutions of the Kuramoto-Sivashinsky equation. The analysis is fully nonlinear at first, and can in principle be carried out to all orders in the small parameter, which is the ratio of the spatial period to a characteristic length of the envelope perturbations. In the linearized regime, we recover a high-order version of the results of Frisch, She, and Thual, which shows that the periodic waves are much more stable than previously expected.

ON THE MOTION THROUGH A VISCOUS FLUID OF A SPHERICAL PARTICLE TOUCHING A PLANE WALL: SLIP BOUNDARY CONDITIONS

A. M. J. Davis, M. T. Kezirian, and H. Brenner 1992 7 p Presented at the 3rd International Symposium on Current Problems in Rheology, Biorheology and Biomechanics, Moscow, Russia, 1-5 Sep. 1992

(Contract DE-FG02-88ER-13896)

(DE93-012540; CONF-9209344-1) Avail: CASI HC A02/MF A01

Understanding the hydrodynamic forces acting upon immersed particles touching surfaces is of central importance in clean room technology and a variety of rheological and biological applications. This paper addresses the translation and rotation of a sphere translating and rotating parallel to a nearby plane wall bounding an otherwise quiescent semi-infinite viscous fluid, while allowing for slip on the wall and/or the sphere. The motivation for disregarding the classical, no-slip boundary condition on solid surfaces arises from an embarrassing discrepancy between theoretical and observed predictions of the translational velocity of a sphere 'rolling' under the influence of gravity down an inclined plane bounding an effectively semi-infinite viscous fluid. According to theory the force and torque on a translating and/or rotating sphere moving parallel to the plane wall become logarithmically infinite with the gap width as the gap between the sphere and well goes to zero. As such, the theoretical conclusion is that the sphere cannot translate down the plane, despite the gravity force that acts to animate it. Experiments, however, reveal that the sphere does, in fact, roll down the plane--at a reproducible mean terminal velocity. In the noninertial, small Reynolds number limit, the experimentally observed drag coefficient was found to be about 8.9 times that given by Stokes law for the unbounded case. This suggests a conventional hydrodynamic wall effect, rather than the logarithmically singular behavior predicted by the theory. It was in an attempt to resolve this glaring contradiction that we have elected here to examine the possible effects of slip. DOE

STUDY OF POSSIBLE MECHANISMS OF INSTABILITY DUE TO HEAT TRANSFER M.S. Thesis [ESTUDO DE POSSIVEIS MECANISMOS DE INSTABILIDADE DEVIDA A TROCAS DE CALOR]

Inocencio GomesdaRocha Sep. 1992 73 p In PORTUGESE

(INPE-5448-TDI/494) Avail: CASI HC A04/MF A01

Possible mechanism causing instabilities in heat generating flows was analyzed, focusing heat-exchanges between an incompressible fluid and the tube walls. Heat transport and temperature profiles were therefore studied in a unidimensional laminar flow occurring in a thin-walled tube without radiative exchanges (thereby leading to different results from those experimentally obtained); a sinusoidal speed field was imposed, there being regions with and without heat-generation of reactive origin within the tube. The resulting coupled equations were solved by up wind finite differences. Values of sinusoidal oscillations in temperature and speed were typical of existing Helmholtz combustors. By adopting a 30-600 Hz oscillating frequency range, and a 0.0028-0.28 Mach range in the fluid speed (the fluid being nitrogen, with properties similar to those of products from combustion of hydrocarbon with air), with an induction time varying from 0.02 to 0.05 sec., no thermal instability in the flow was observed. AN ANALYTICAL INVESTIGATION OF TRANSIENT EFFECTS ON REWETTING OF HEATED THIN FLAT PLATES

J. A. Platt Aug. 1993 11 p Presented at the Fundamentals of Heat Transfer in a Microgravity Environment, ASME 1993 Winter Annual Meeting, New Orleans, LA, 28 Nov. - 3 Dec. 1993; sponsored by ASME

(RTOP 674-24-05)

(NASA-TM-106120; E-7779; NAS 1.15:106120) Avail: CASI HC A03/MF A01

The rewetting of a hot surface is a problem of prime importance in the microgravity application of heat pipe technology, where rewetting controls the time before operations can be re-established following depriming of a heat pipe. Rewetting is also important in the nuclear industry (in predicting behavior during loss-of-coolant accidents), as well as in the chemical and petrochemical industries. Recently Chan and Zhang have presented a closed-form solution for the determination of the rewetting speed of a liquid film flowing over a finite (but long) hot plate subject to uniform heating. Unfortunately, their physically unreasonable initial conditions preclude a meaningful analysis of start-up transient behavior. A new nondimensionalization and closed-form solution for an infinitely-long, uniformly-heated plate is presented. Realistic initial conditions (step change in temperature across the wetting front) and boundary conditions (no spatial temperature gradients infinitely far from the wetting front) are employed. The effects of parametric variation on the resulting simpler closed-form solution are presented and compared with the predictions of a 'quasi-steady' model. The time to reach steady-state rewetting is found to be a strong

function of the initial dry-region plate temperature. For heated plates it is found that in most cases the effect of the transient response terms cannot be neglected, even for large times. Author (revised)

INTEGRATION OF VISCOUS EFFECTS INTO INVISCID COMPUTATIONAL METHODS Final Report
Joseph Katz Aug. 1990 4 p
(Contract NCC2-458)
(NASA-CR-193677; NAS 1.26:193677; SDSU-CEP-524067) Avail: CASI HC A01/MF A01

A variety of practical fluid dynamic problems related to the low-speed, high Reynolds number flow over aircraft and ground vehicles fall in a category where some simplified mathematical models become applicable. This provides the fluid dynamicists with a more economical computational tool, compared to the alternative solution of the Navier Stokes equations. The objective was to provide a brief survey of some of the viscous boundary layer solution methods and to propose a method for coupling between the inviscid outer flow and the viscous boundary layer solutions. Results of this survey and details of the viscous/inviscid flow coupling efforts are presented. Author (revised)

TWO-DIMENSIONAL NAVIER-STOKES HEAT TRANSFER ANALYSIS FOR ROUGH TURBINE BLADES
R. J. Boyle and K. C. Civinskas Jun. 1991 13 p Presented at the 27th Joint Propulsion Conference and Exhibit, Sacramento, CA, 24-27 Jun. 1991; sponsored by AIAA, SAE, and ASME Previously announced in IAA as A91-45790 Prepared in cooperation with ARL, Cleveland, OH
(RTOP 505-62-52)
(NASA-TM-106008; E-7755; NAS 1.15:106008; ARL-MR-14; AIAA Paper 91-2129) Avail: CASI HC A03/MF A01

A quasi-three-dimensional thin-layer Navier-Stokes analysis was used to predict heat transfer to rough surfaces. Comparisons are made between predicted and experimental heat transfer for turbine blades and flat plates of known roughness. The effect of surface roughness on heat transfer was modeled using a mixing length approach. The effect of near-wall grid spacing and convergence criteria on the accuracy of the heat transfer predictions are examined. An eddy viscosity mixing length model having an inner and outer layer was used. A discussion of the appropriate model for the crossover between the inner and outer layers is included. The analytic results are compared with experimental data for both flat plates and turbine blade geometries. Comparisons between predicted and experimental heat transfer showed that a modeling roughness effects using a modified mixing length approach results in good predictions of the trends in heat transfer due to roughness. LARGE-EDDY SIMULATION OF LAMINAR-TURBULENT BREAKDOWN AT HIGH SPEEDS WITH DYNAMIC SUBGRID-SCALE MODELING
Nabil M. El-Hady Washington NASA Aug. 1993 60 p
(Contract NAS1-19320; RTOP 505-59-50-01)
(NASA-CR-4533; NAS 1.15:4533) Avail: CASI HC A04/MF A01

The laminar-turbulent breakdown of a boundary-layer flow along a hollow cylinder at Mach 4.5 is investigated with large-eddy simulation. The subgrid scales are modeled dynamically, where the model coefficients are determined from the local resolved field. The behavior of the dynamic-model coefficients is investigated through both an a priori test with direct numerical simulation data for the same case and a complete large-eddy simulation. Both formulations proposed by Germano et al. and Lilly are used for the determination of unique coefficients for the dynamic model and their results are compared and assessed. The behavior and the energy cascade of the subgrid-scale field structure are investigated at various stages of the transition process. The investigations are able to duplicate a high-speed transition phenomenon observed in experiments and explained only recently by the direct numerical simulations of Pruett and Zang, which is the appearance of 'rope-like' waves. The nonlinear evolution and breakdown of the laminar boundary layer and the structure of the flow field during the transition process were also investigated. Author (revised)

TRANSITION PREDICTION AND CONTROL IN SUBSONIC FLOW OVER A HUMP
Jamal A. Masad and Venkit Iyer (Vigyan Research Associates, Inc., Hampton, VA.) Washington NASA Sep. 1993 57 p
(Contracts NAS1-19299; NAS1-19672; RTOP 537-03-23-03)
(NASA-CR-4543; NAS 1.26:4543) Avail: CASI HC A04/MF A01

The influence of a surface roughness element in the form of a two-dimensional hump on the transition location in a two-dimensional subsonic flow with a free-stream Mach number up to 0.8 is evaluated. Linear stability theory, coupled with the N-factor transition criterion, is used in the evaluation. The mean flow over the hump is calculated by solving the interacting boundary-layer equations; the viscous-inviscid coupling is taken into consideration, and the flow is solved within the separation bubble. The effects of hump height, length, location, and shape; unit Reynolds number; free-stream Mach number, continuous suction level; location of a suction strip; continuous cooling level; and location of a heating strip on the transition location are evaluated. The N-factor criterion predictions agree well with the experimental correlation of Fage; in addition, the N-factor criterion is more general and powerful than experimental correlations. The theoretically predicted effects of the hump's parameters and flow conditions on transition location are consistent and in agreement with both wind-tunnel and flight observations. Author

SURROGATES FOR NUMERICAL SIMULATIONS; OPTIMIZATION OF EDDY-PROMOTER HEAT EXCHANGERS Final Report
Anthony T. Patera (Massachusetts Inst. of Tech., Cambridge.) and Anthony Patera (Massachusetts Inst. of Tech., Cambridge.) Washington NASA Aug. 1993 56 p Submitted for publication
(Contracts NAS1-19480; N00014-91-J-1889; N00014-90-J-4124; N00014-89-J-1610; RTOP 505-90-52-01)
(NASA-CR-191510; NAS 1.26:191510; ICASE-93-50) Avail: CASI HC A04/MF A01

Although the advent of fast and inexpensive parallel computers has rendered numerous previously intractable calculations feasible, many numerical simulations remain too resource-intensive to be directly inserted in engineering optimization efforts. An attractive alternative to direct insertion considers models for computational systems: the expensive simulation is evoked only to construct and validate a simplified, input-output model; this simplified input-output model then serves as a simulation surrogate in subsequent engineering optimization studies. A simple 'Bayesian-validated' statistical framework for the construction, validation, and purposive application of static computer simulation surrogates is presented. As an example, dissipation-transport optimization of laminar-flow eddy-promoter heat exchangers are considered: parallel spectral element Navier-Stokes calculations serve to construct and validate surrogates for the flowrate and Nusselt number; these surrogates then represent the originating Navier-Stokes equations in the ensuing design process. THE THREE-DIMENSIONAL FLOW PAST A RAPIDLY ROTATING CIRCULAR CYLINDER

James P. Denier (New South Wales Univ., Sydney, Australia.) and Peter W. Duck (Manchester Univ., England.) Washington Aug. 1993 19 p (Contract NAS1-19480; RTOP 505-90-52-01)

(NASA-CR-191512; ICASE-93-52; NAS 1.26:191512) Avail: CASI HC A03/MF A01

The high Reynolds number (Re) flow past a rapidly rotating circular cylinder is investigated. The rotation rate of the cylinder is allowed to vary (slightly) along the axis of the cylinder, thereby provoking three-dimensional flow disturbances, which are shown to involve relatively massive (O(Re)) velocity perturbations to the flow away from the cylinder surface. Additionally, three integral conditions, analogous to the single condition determined in two dimensions by Batchelor, are derived, based on the condition of periodicity in the azimuthal direction. PINCHING SOLUTIONS OF SLENDER CYLINDRICAL JETS Final Report

Demetrios T. Papageorgiou (New Jersey Inst. of Tech., Newark.) and Oscar Orellana (Universidad Tecnica Federico Santa Maria, Valparaiso, Chile.) Washington NASA Jun. 1993 29 p Submitted for publication

(Contracts NAS1-19480; NAS1-18605; RTOP 505-90-52-01; FNDCT-246/91)

(NASA-CR-191482; NAS 1.26:191482; ICASE-93-32) Avail: CASI HC A03/MF A01

Simplified equations for slender jets are derived for a circular jet of one fluid flowing into an ambient second fluid, the flow being confined in a circular tank. Inviscid flows are studied which include both surface tension effects and Kelvin-Helmholtz instability. For slender jets a coupled nonlinear system of equations is found for the jet shape and the axial velocity jump across it. The equations can break down after a finite time and similarity solutions are constructed, and studied analytically and numerically. The break-ups found pertain to the jet pinching after a finite time, without violation of the slender jet ansatz. The system is conservative and admissible singular solutions are those which conserve the total energy, mass, and momentum. Such solutions are constructed analytically and numerically, and in the case of vortex sheets with no surface tension certain solutions are given in closed form. Author (revised)

FUNDAMENTAL STUDY OF SHOCK WAVE/TURBULENT BOUNDARY LAYER INTERACTIONS WITH PASSIVE CONTROL IN TRANSONIC FLOWS

Reynald Bur (Office National d'Etudes et de Recherches Aerospatiales, Paris, France.) May 1993 270 p Transl. into ENGLISH of Etude fondamentale sure le controle passif de l'interaction onde de choc/couche limite turbulente en ecoulement transsonique (Paris, France, ONERA), 1991 p 1-238 Original language document announced as N92-19932

(ESA-TT-1278; ONERA-NT-1991-9; ETN-93-94583) Avail: CASI HC A12/MF A03

The techniques for controlling shock wave/turbulent boundary layer interaction are reviewed. A passive control device makes it possible to improve the performance of airfoils at transonic velocities. An interaction subjected to passive control was performed in a transonic channel. The flow is described by means of Schlieren visualization, measurements of pressure on the walls of the duct and two dimensional laser velocimetry. A momentum balance carried out in the control region made it possible to infer configurations for which the friction drag is reduced by comparison with the reference case without control. The theoretical study is based on a boundary layer type approach using the first order Prandtl equations. Experimental results obtained for the reference case and a case with control are compared. THE EFFECT OF CROSSFLOW ON TAYLOR VORTICES: A MODEL PROBLEM Final Report

S. R. Otto and Andrew P. Bassom (Exeter Univ., England.) Washington Jun. 1993 21 p Submitted for publication

(Contract NAS1-19480; RTOP 505-90-52-01)

(NASA-CR-191487; NAS 1.26:191487; ICASE-93-33) Avail: CASI HC A03/MF A01

A number of practically relevant problems involving the impulsive motion or the rapid rotation of bodies immersed in fluid are susceptible to vortex-like instability modes. Depending upon the configuration of any particular problem the stability properties of any high-wavenumber vortices can take on one of two distinct forms. One of these is akin to the structure of Gortler vortices in boundary layer flows while the other is similar to the situation for classical Taylor vortices. Both the Gortler and Taylor problems have been extensively studied when crossflow effects are excluded from the underlying base flows. Recently, studies were made concerning the influence of crossflow on Gortler modes and a linearized stability analysis is used to examine crossflow properties for the Taylor mode. This work allows us to identify the most unstable vortex as the crossflow component increases and it is shown how, like the Gortler case, only a very small crossflow component is required in order to completely stabilize the flow. Our investigation forms the basis for an extension to the nonlinear problem and is of potential applicability to a range of pertinent flows.

INTERACTING SCALES AND ENERGY TRANSFER IN ISOTROPIC TURBULENCE Final Report

Ye Zhou (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.) Washington Jun. 1993 37 p Submitted for publication

(Contract NAS1-19480; RTOP 505-90-52-01)

(NASA-CR-191477; NAS 1.26:191477; ICASE-93-28) Avail: CASI HC A03/MF A01

The dependence of the energy transfer process on the disparity of the interacting scales is investigated in the inertial and far-dissipation ranges of isotropic turbulence. The strategy for generating the simulated flow fields and the choice of a disparity parameter to characterize the scaling of the interactions is discussed. The inertial range is found to be dominated by relatively local interactions, in agreement with the Kolmogorov assumption. The far-dissipation is found to be dominated by relatively non-local interactions, supporting the classical notion that the far-dissipation range is slaved to the Kolmogorov scales. The measured energy transfer is compared with the classical models of Heisenberg, Obukhov, and the more detailed analysis of Tennekes and Lumley. The energy transfer statistics measured in the numerically simulated flows are found to be nearly self-similar for wave numbers in the inertial range. Using the self-similar form measured within the limited scale range of the simulation, an 'ideal' energy transfer function and the corresponding energy flux rate for an inertial range of infinite extent are constructed. From this flux rate, the Kolmogorov constant is calculated to be 1.5, in excellent agreement with experiments.

THE TRANSIENT BEHAVIOR OF A BOUNDARY LAYER EXPOSED TO UNIFORM SUCTION M.S. Thesis

Tomer Bachar Mar. 1992 119 p In HEBREW
(ITN-93-85205) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

An experimental investigation in a low-turbulence wind tunnel was performed to study the influence of uniform suction on laminar and turbulent boundary layers. A zero-pressure-gradient boundary layer was developed over a flat plate with a porous section, across which the suction system maintained a uniform suction, which could be switched on and off abruptly. Throughout the experiments, a constant freestream was maintained. The basic boundary layer was either laminar Blasius-like or fully turbulent. The latter mode was achieved by using distributed roughness to trip the flow. The controlled suction rates varied between 0 and 0.45%. The influence of the suction on the streamwise velocity distributions was investigated along the line of symmetry of the flat plate, in steady-state and transient flows. This was done by measuring the longitudinal velocity component with a hot wire. The influence of suction on the boundary layer was found to be negligible upstream of the porous plate; it modified the velocity profile to an asymptotic profile over the porous region, and shifted the virtual origin of the boundary layer downstream from the porous plate. These sections were separated by transition zones, in which the flow adapted to the approaching condition. The length of each interface zone depended on the suction rate. An exponential temporal function was found to be a good approximation to the boundary layer response to sudden changes in suction. The power of the function depended on the flow characteristics and the suction rate. The relative impact of suction is stronger for the laminar boundary layer, while the turbulent boundary layer responds faster to a sudden suction. Author (ISA)

CAPILLARY SURFACES IN A WEDGE: DIFFERING CONTACT ANGLES
P. Concus and R. Finn (Stanford Univ., CA.) Apr. 1993 12 p Presented at the International Symposium on Microgravity Science and Application, Beijing, China, 10-13 May 1993
(Contract DE-AC03-76SF-00098)
(DE93-013903; LBL-33995; CONF-9305197-1) Avail: CASI HC A03/MF A01

The possible zero-gravity equilibrium configurations of capillary surfaces u(x,y) in cylindrical containers whose sections are (wedge) domains with corners are investigated mathematically, for the case in which the contact angles on the two sides of the wedge may differ. In such a situation the behavior can depart in significant qualitative ways from that for which the contact angles on the two sides are the same. Conditions are described under which such qualitative changes must occur. Numerically computed surfaces are depicted to indicate the behavior. DOE

NUMERICAL SIMULATIONS AND EXPERIMENTS ON PHYSICS OF HIGH MACH NUMBER SHOCKWAVE: TURBULENT FLOW INTERACTIONS
A. C. Buckingham and J. Grun Dec. 1992 10 p Presented at the 4th International Workshop on the Physics of Compressible Turbulent Mixing, Cambridge, England, 29 Mar. - 1 Apr. 1993
(Contract W-7405-eng-48)
(DE93-013424; UCRL-JC-112287; CONF-9303126-3) Avail: CASI HC A02/MF A01

When a shock moves into and interacts with an existing turbulent field, a substantial enhancement of the after-shock turbulent intensity and a simultaneous distortion and realignment of the tensor stress rate field and associated tensor stress field results. Component mixing, advective transport, and diffusion, as well as associated momentum and energy dissipation, are intensified over their pre-shocked levels. A combination of low preshocked turbulent intensity and strong shocks (e.g. shock Mach numbers substantially greater than one) produces the most pronounced interactive change in the turbulence level. In contrast, when a weak shock (Mach number only slightly greater than one) moves through relatively intense upstream turbulence, the turbulence change is modest, but the dynamical distortion and erratic motion of the shock front is much more pronounced. It is a commonly held view that if the interactive shock Mach number is in the hypersonic range (shock Mach numbers equal to or greater than about 6), rapid reinforcement of shock strength at the front by non-linear pressure field interactions and consequent self-healing of shock front geometric irregularity would act to suppress front distortion and also suppress the influence of the shock interactions on the surrounding turbulence. In the present work, recent experiments, numerical large eddy simulations (LES), and analysis are presented which contradict this notion. This work suggests that pronounced shock front distortion and substantial interactive modification of the turbulence persists even for shocks propagating at shock Mach numbers well in excess of 100. (DE93-013425; UCRL-JC-112286; CONF-930785-1) Avail: CASI HC A03/MF A01

We continue to study the influence of dynamic shock wave interactions on turbulence. The interactions may significantly increase turbulent energy and Reynolds stress. Strong support for tensor amplification is supplied by the sharp, transiently distorted strain field in the immediate neighborhood of the shock. Beyond this, there develops a gradual decay to a new, more modestly amplified state relative to the pre-shocked level. Practical interest is centered on the significantly altered, albeit shock localized, post-shock turbulent kinetic energy, eddy transport, eddy component mixing and diffusion, wall shear, and heat transfer. In the shock interaction and post-shock region, compressible two dimensional large eddy simulations (LES) are applied. A compressibility modified Smagorinsky model is adapted to represent the non-resolved sub-grid scales. Favre mass-weighted average space and time discretized compressible Navier-Stokes equations are used to represent the explicitly resolved grid scale motions. Predicted amplification levels, modal energy partition, shock translational to turbulence kinetic energy transfer, and viscoelastic response of turbulence to shock interaction are examined in comparison with available experimental evidence. A two-band dynamic eddy viscosity model representing the unresolved subgrid scale field is a possible replacement for the Smagorinsky model. Improvement is sought for predictions in the near wall region, under the influence of stochastic subgrid scale backscatter, and in the neighborhood of the shock. Wall-bounded supersonic compression corner flow experiments and hypersonic cylindrical shock wave turbulence interaction experiments are used as trial cases for test and comparison of the two classes of subgrid scale models. EXPERIMENTAL DETERMINATION OF DROPLETS LOCAL MEAN DIAMETER OF A SPRAG FROM IMPINGING JETS Thesis [DETERMINACAO EXPERIMENTAL DO DIAMETRO MEDIO LOCAL DAS GOTAS DE UM SPRAY DE UM INJETOR DO TIPO JATOS COLIDENTES]
Luiz Carlos deQueiroz May 1992 64 p In PORTUGESE
(INPE-5469-TDI/500) Avail: CASI HC A04/MF A01

Reviews of the light scattering theory and of the droplet size distribution modeling from impinging jets by Couto et al are presented. A technique based on the light diffractive scattering was used to determine the Sauter mean diameter of drops in water sprays. Spray produced by impinging jets with the following total impinging angles: 60 deg, 70 deg, and 90 deg. The experimental results obtained showed a agreement to the theoretical diameters. A MULTIPLE-SCALE TURBULENCE MODEL FOR INCOMPRESSIBLE FLOW
B. S. Duncan (Sverdrup Technology, Inc., Brook Park, OH.), W. W. Liou, and T. H. Shih Jan. 1993 14 p Presented at the 31st Aerospace Sciences Meeting and Exhibit, Reno, NV, 11-14 Jan. 1993; sponsored by AIAA See also A93-24228
(RTOP 505-62-40)
(NASA-TM-106113; ICOMP-93-11; CMOTT-93-3; E-7765; NAS 1.15:106113) Avail: CASI HC A03/MF A01

A multiple-scale eddy viscosity model is described. This model splits

the energy spectrum into a high wave number regime and a low wave number regime. Dividing the energy spectrum into multiple regimes simplistically emulates the cascade of energy through the turbulence spectrum. The constraints on the model coefficients are determined by examining decaying turbulence and homogeneous turbulence. A direct link between the partitioned energies and the energy transfer process is established through the coefficients. This new model was calibrated and tested for boundary-free turbulent shear flows. Calculations of mean and turbulent properties show good agreement with experimental data for two mixing layers, a plane jet and a round jet. Author (revised)

A MULTIPHASE MODEL FOR SHOCK-INDUCED FLOW IN LOW DENSITY FOAM
M. R. Baer 1993 6 p Presented at the 19th International Symposium on Shock Waves, Marseille, France, 26-30 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-013767; SAND-93-0725C; CONF-930788-1) Avail: CASI HC A02/MF A01

A multiphase mixture model is applied to describe shocked-induced flow in deformable low-density foam. This model includes interphase drag and heat transfer and all phases are treated as compressible. Volume fraction is represented as an independent kinematic variable, and the entropy inequality suggests a thermodynamically-admissable evolutionary equation to describe rate-dependent compaction. This multiphase model has been applied to shock tube experiments in the study of normal shock impingement on a wall-supported low density porous layer. Numerical solution of the multiphase flow equations employs a high resolution adaptive finite element method which accurately resolves contact surfaces and shock interactions. Additional studies are presented in an investigation of the effect of initial gas pressure in the foam layer, the shock interaction on multiple layers of foam, and the shock-induced flow in an unsupported foam layer. A PRIORI ERROR ESTIMATES FOR AN hp-VERSION OF THE DISCONTINUOUS GALERKIN METHOD FOR HYPERBOLIC CONSERVATION LAWS
Kim S. Bey and J. Tinsley Oden (Texas Univ., Austin.) Jun. 1993 27 p
(RTOP 505-43-31)
(NASA-TM-108993; NAS 1.15:108993) Avail: CASI HC A03/MF A01

A priori error estimates are derived for hp-versions of the finite element method for discontinuous Galerkin approximations of a model class of linear, scalar, first-order hyperbolic conservation laws. These estimates are derived in a mesh dependent norm in which the coefficients depend upon both the local mesh size h(sub K) and a number p(sub k) which can be identified with the spectral order of the local approximations over each element. Rectangular flow passages with interrupted surface configurations are often found in heat transfer equipment such as compact heat exchanger cores widely used in automobiles, spacecraft, aircraft, and the power and process industries. Experimental and numerical investigations of turbulent spatially periodic fully developed flows in straight ducts of rectangular cross section with interrupted plate inserts are presented. A computer code, based on a finite volume method and incorporating a low Reynolds number turbulence model, was developed, tested, and used in the investigation. The experimental work was aimed at obtaining accurate and complete data that would allow fair evaluation of the numerical model and lead to an enhanced understanding of spatially periodic fully developed turbulent flows. Such flows in three different interrupted plate ducts were investigated. The results presented include module friction factor versus Reynolds number plots, plate surface streamline photographs, and plots of intramodular time-mean wall static pressure distributions. The details and implications of these results are discussed. CISTI

The statistical approach of maximal randomness of the velocity field is extended for the case of decaying turbulence with spontaneous parity violation. The set of self-consistent equations in one-loop approximation is obtained. It is without the infrared and ultraviolet divergences and has a scaling solution which leads to Kolmogorov spectrum in inertial range of wave numbers K and gives the well-known time-dependence laws for integral turbulence scale r(sub c)(t) approx t(sup 2/5) and turbulent energy per mass e(t) approx t(sup -6/5). The set of equations for scaling functions of energy and helicity spectral density, depending only on dimensionless parameter kr(sub c), is presented. DOE

THERMAL GRAVITATIONAL MODELLING AND SCALING OF TWO-PHASE HEAT TRANSPORT SYSTEMS: SIMILARITY CONSIDERATIONS AND USEFUL EQUATIONS PREDICTIONS VERSUS EXPERIMENTAL RESULTS
A. A. M. Delil 30 Dec. 1991 26 p Presented at 1st European Symposium on Fluids in Space, Ajaccio, France, 18-22 Nov. 1991
(NLR-TP-91477-U; ETN-93-94343) Avail: CASI HC A03/MF A01

A review on various aspects of thermal gravitational scaling of spacecraft two phase heat transport systems is presented. Supporting similarity considerations, based on dimension analysis, and useful equations and correlations are given. The assessment of the applicability (validity and restrictions) of the modeling and scaling approach is supported by a comparison of two phase flow pressure drops measured under low gravity conditions and modeling predictions. Terrestrial scaling experiments with an ammonia test rig are identified for the support of the development of the ESA capillary pumped two phase ammonia experiment in Get Away Special G-557 and the development of the mechanically pumped ESA R114 Two Phase Heat Transport System (TPHTS). A HIGH-RESOLUTION LAX-FRIEDRICHS SCHEME FOR HYPERBOLIC CONSERVATION LAWS WITH SOURCE TERMS: APPLICATION TO SHALLOW WATER EQUATIONS
Gerhard Erbes 25 Mar. 1992 51 p
(DM-62; ETN-93-94487) Avail: CASI HC A04/MF A01

A recently developed high resolution, non oscillatory staggered method, based upon the Lax-Friedrichs scheme, for hyperbolic conservation laws, is considered. The staggered method is extended to include source terms, and it is also shown how to implement multiple dimensions. The advantage of using a staggered method is that Riemann problems no longer need to be solved. Numerical experiments are performed with the shallow water equations for which the staggered method yields sharp nonoscillatory shocks while retaining a high accuracy in regions where the flow is smooth. The accuracy obtained with the staggered method is significantly higher than in conventional finite difference schemes used in the field of meteorology. ESA

EFFECTS OF SURFACE THERMAL FORCING ON STRATIFIED FLOW PAST AN ISOLATED OBSTACLE Ph.D. Thesis
Jon Reisner 1992 104 p
Avail: Univ. Microfilms Order No. DA9311529

The present study investigates basic aspects of the flow of a density-stratified fluid past three-dimensional obstacles for Froude number is approximately O(1) and isolated surface thermal forcing representative of diurnally varying mesoscale flows past mountainous islands such as Hawaii. In order to minimize parameter space, we have excluded the effects of friction, rotation, nonuniform ambient flow, and the complexities of realistic surface boundary layer and terrain. Through simple scaling arguments, we deduce that the parameter eta* controls thermally forced flows for a given Froude number, and we provide crude estimates of a flow response for a range of eta*. The principal question addressed is for what values of eta* will a transition occur from the low-Froude-number flow regime, characterized by the stagnation and splitting of the lower upwind flow, to the regime in which flow passes over rather than around the obstacle. We show that the linear theory captures such a tendency consistently with simple scaling arguments. To provide quantitative measures of flow variability with the Froude number and eta*, we employ an efficient isentropic numerical code and summarize the results of numerous simulations in the form of a regime diagram. The principal result is a simple criterion for the transition of a heated flow from the blocked to unblocked flow regime. We illustrate the relevance of the idealized study to natural flows with an example of applications to a flow past the Hawaiian Archipelago. Author

HIGH FREESTREAM TURBULENCE EFFECTS ON THE TRANSPORT OF HEAT AND MOMENTUM Ph.D. Thesis
Karen Ann Thole 1992 279 p
Avail: Univ. Microfilms Order No. DA9309297

Understanding high freestream turbulence effects on the transport of heat and momentum is needed for better predictive schemes. This dissertation presents the effects of very high freestream turbulence levels, between Tu equals 10 percent and 20 percent, on surface heat transfer and skin friction in terms of the turbulent transport of heat and momentum. Both the velocity and thermal fields are quantified for a boundary layer influenced by high freestream turbulence and are compared to a boundary layer with negligible freestream turbulence. In addition to quantifying the mean and rms values of temperature and velocity, the turbulent heat flux profiles are quantified through simultaneous temperature/velocity measurements. Spectra and length scales for both temperature and velocity are also quantified in the freestream and throughout the boundary layer. The results of this study indicate that scaling the heat transfer en-ancement is best accomplished using St' which uses the maximum rms streamwise velocity as the velocity scale in the Stanton number. Similarly, scaling the skin friction enhancement is best accomplished using Cf' which also uses the maximum rms streamwise velocity as the velocity in the skin friction coefficient. In the case of St', a constant value occurs for all turbulence levels and was found to be independent of turbulent length scales and momentum Reynolds numbers. Cf' remains constant for turbulence levels less than 15 percent, but then decreases as the turbulence levels increase. When using the other scaling parameters that depend on turbulence level and length scale, more consistent trends were found for the integral length scale rather than the dissipation length scale. The present data indicate that a highly turbulent freestream does not enhance the skin friction as much as the heat transfer. However, the turbulent transport of momentum does scale with the surface shear stress and the turbulent transport of heat does scale with the surface heat flux. Thus, these turbulent transport mechanisms are similarly affected by the high freestream turbulence. The reduced shear stress enhancement is attributed to large-scale, inactive motions from the highly turbulent freestream which penetrate into the turbulent boundary layer, displace the active motions, and reduce the average shear stress. These actions result in reduced correlation of the turbulent fluctuations which counter-balances the enhancement effect of increased turbulence levels so that there is no net increase in wall shear. However, these inactive motions have less effect on the normal heat flux. Therefore, heat transfer continues to be enhanced as turbulence levels increase.

NUMERICAL SIMULATIONS OF UNSTEADY FLOWS IN TURBOMACHINES Ph.D. Thesis
Daniel Joseph Dorney 1992 314 p
Avail: Univ. Microfilms Order No. DA9311624

The performance of axial and centrifugal turbomachines is significantly affected by the presence of unsteady and viscous flow mechanisms. Most contemporary design systems, however, use steady or linearized unsteady inviscid flow analyses to generate new blade shapes. In an effort to increase the understanding of unsteady viscous flows in turbomachinery blade rows, and to determine the limitations of linearized inviscid flow analyses, a two-part investigation was conducted. In the first portion of this investigation, a nonlinear viscous flow analysis was developed for the prediction of unsteady flows in two dimensional axial turbomachinery blade rows. The boundary conditions were formulated to allow the specification of vortical, entropic and acoustic excitations at the inlet, and acoustic excitations at exit, of a cascade. Numerical simulations were performed for flat plate and compressor exit guide vane cascades, and the predicted results were compared with solutions from classical linearized theory and linearized inviscid flow analysis. The unsteady pressure fields predicted with the current analysis showed close agreement with the linearized solutions for low to moderate temporal frequency vortical and acoustic excitations. As the temporal frequency of the excitations was increased, nonlinear effects caused discrepancies to develop between the linearized and Navier-Stokes solution sets. The inclusion of viscosity had a significant impact on the unsteady vorticity field, but only a minimal effect on the unsteady pressure field. In the second part of this investigation, a quasi-three-dimensional Navier-Stokes analysis was modified and applied to flows in centrifugal turbomachinery blade rows. Inviscid and viscous flow simulations were performed for a centrifugal impeller at three operating conditions. By comparing the predicted and experimental circumferential distributions of the relative frame velocity and flow angle downstream of the impeller, it was hypothesized that in the experiments the end secondary flows energize the impeller suction surface boundary making the local flow behave like an inviscid fluid. The performance curve generated from the viscous calculations showed close agreement with the experimental data. Author

TOPICS ON SPATIALLY HIGH-ORDER ACCURATE METHODS AND PRE-CONDITIONING FOR THE NAVIER-STOKES EQUATIONS WITH FINITE-RATE CHEMISTRY Ph.D. Thesis
Andrew Grady Godfrey 1992 237 p
Avail: Univ. Microfilms Order No. DA9311573

This dissertation discusses two aspects of computational fluid dynamics: high-order spatial accuracy and convergence-rate acceleration through system preconditioning. Concerning high-order accuracy, the computational qualities of various spatial methods for the finite-volume solution of the Euler equations are presented. The two-dimensional essentially non-oscillatory (ENO), k-exact, and dimensionally split ENO reconstruction operators are discussed and compared in terms of reconstruction and solution accuracy and computational cost. Standard variable extrapolation methods are included for completeness. Inherent steady-state convergence difficulties are demonstrated for adaptive-stencil algorithms. Methods for reconstruction error analysis are presented and an exact solution to the heat equation is used as an example. Numerical experiments presented include the Ringleb flow for numerical accuracy and a shock-reflection problem. A vortex-shock interaction demonstrates the ability of the ENO scheme to excel in capturing unsteady high-frequency flow physics. Concerning convergence-rate acceleration, characteristic-wave preconditioning is extended to include generalized finite-rate chemistry with non-equilibrium thermodynamics. Additionally, the proper preconditioning for the one-dimensional Navier-Stokes equations is presented. Eigenvalue stiffness is resolved and convergence-rate acceleration is demonstrated over the entire Mach-number range from the incompressible to the hypersonic. Specific benefits are realized at low and transonic flow speeds. The extended preconditioning matrix accounts for thermal and chemical non-equilibrium and its implementation is explained for both explicit and implicit time marching. The effects of high-order spatial accuracy and various flux splittings are investigated. Numerical analysis reveals the possible theoretical improvements from using preconditioning at all Mach numbers. Numerical results confirm the expectations from the analysis. The

preconditioning matrix is applied with dual time stepping to obtain arbitrarily high-order accurate temporal solutions within an implicit formulation. Representative test cases include flows with previously troublesome embedded high-condition-number regions. Author

AN EXPERIMENTAL INVESTIGATION OF SHOCK WAVE/VORTEX INTERACTION Ph.D. Thesis
Louis Nicholas Cattafesta, III 1992 279 p
Avail: Univ. Microfilms Order No. DA9311604

Although shock wave/vortex interaction is a basic and important fluid dynamics problem, very little research has been conducted on this topic. Therefore, a detailed experimental study of the interaction between a supersonic streamwise turbulent vortex and a shock wave has been carried out at the Penn State Gas Dynamics Laboratory. A vortex is produced by replaceable swirl vanes located upstream of the throat of various converging-diverging nozzles. The supersonic vortex is then injected into either a coflowing supersonic stream or ambient air. The structure of the isolated vortex is investigated in a supersonic wind tunnel using miniature, fast-response, five-hole and total temperature probes and in a free jet using Laser Doppler Velocimetry. The cases tested have unit Reynolds numbers in excess of 25 million per meter, axial Mach numbers ranging from 2.5 to 4.0, and peak tangential Mach numbers from 0 (i.e. a pure jet) to about 0.7. The results show that the typical supersonic wake-like vortex consists of a non-isentropic, rotational core, where the reduced circulation distribution is self-similar, and an outer isentropic, irrotational region. The vortex core is also a region of significant turbulent fluctuations. Radial profiles of turbulent kinetic energy and axial-tangential Reynolds stress are presented. The interactions between the vortex and both oblique and normal shock waves are investigated using nonintrusive optical diagnostics (i.e. schlieren, Planar Laser Scattering, and Laser Doppler Velocimetry). Of the various types, two Mach 2.5 overexpanded-nozzle Mach-disc interactions are examined in detail. Below a certain vortex strength, a 'weak' interaction exists in which the normal shock is perturbed locally into an unsteady 'bubble' shock near the vortex axis, but vortex breakdown (i.e. a stagnation point) does not occur. For stronger vortices, a random unsteady 'strong' interaction results that causes vortex breakdown. The vortex core reforms downstream of the rear stagnation point, and the reduced circulation distribution once again becomes self-similar in this region. A new model of this interaction is proposed. Finally, a curve defining the approximate limits of supersonic vortex breakdown is presented. Author

PASSAGE-AVERAGED APPROXIMATION OF TURBOMACHINERY FLOWS USING VORTICITY-POTENTIAL METHOD Ph.D. Thesis
Xudong Zhang 1991 206 p
(ISBN-0-315-72716-0) Avail: Univ. Microfilms Order No. DANN72716

A physical and mathematical model based on a passage-averaged vorticity-potential formulation for the simulation of flows in a rotor-stator stage of a turbomachine is presented. The passage-averaged governing equations were developed by taking into account the viscous effects through the three-dimensional Navier-Stokes equations applied to flows within blade rows. An implicit three-dimensional algorithm was also developed for solving, within the blade passages, the three-dimensional Navier-Stokes equations in terms of vorticity, scalar and vector potentials. This algorithm is coupled with the passage-averaged governing equations to form a closed set of equations describing rotor-stator flow interactions. Validation of the numerical algorithms is primarily performed on a number of test problems, including the developing flows in a channel rotating annulus, straight and curved ducts. A more realistic test computation for an impeller with planar blades completes the validation. The numerical results are compared with available analytical solutions and experimental data. Dissert. Abstr.

NUMERICAL SIMULATION OF STEADY THREE-DIMENSIONAL FLOWS IN AXIAL TURBOMACHINERY BLADEROWS Ph.D. Thesis
Anton Herman Basson 1992 275 p
Avail: Univ. Microfilms Order No. DA9311593

The formulation for and application of a numerical model for low Mach number steady three-dimensional flows in axial turbomachinery blade rows is presented. The formulation considered here includes an efficient grid generation scheme (particularly suited to computational grids for the analysis of turbulent turbomachinery flows) and a semi-implicit, pressure-based computational fluid dynamics scheme that directly includes artificial dissipation, applicable to viscous and inviscid flows. The grid generation technique uses a combination of algebraic and elliptic methods, in conjunction with the Minimal Residual Method, to economically generate smooth structured grids. For typical H-grids in turbomachinery bladerows, when compared to a purely elliptic grid generation scheme, the presented grid generation scheme produces grids with much improved smoothness near the leading and trailing edges, allows the use of small near wall grid spacing required by low Reynolds number turbulence models, and maintains orthogonality of the grid near the solid boundaries even for high flow angle cascades. A specialized embedded H-grid for application particularly to tip clearance flows is presented. This topology smoothly discretizes the domain without modifying the tip shape, while requiring only minor modifications to H-grid flow solvers. Better quantitative modeling of the tip clearance vortex structure than that obtained with a pinched tip approximation is demonstrated. The formulation of artificial dissipation terms for a semi-implicit, pressure-based (SIMPLE type) flow solver, is presented. It is applied to both the Euler and the Navier-Stokes equations, expressed in generalized coordinates using a non-staggered grid. This formulation is compared to some SIMPLE and time marching formulations, revealing the artificial dissipation inherent in some commonly used semi-implicit formulations. The effect of the amount of dissipation on the accuracy of the solution and the convergence rate is quantitatively demonstrated for a number of flow cases. The ability of the formulation to model complex steady turbomachinery flows is demonstrated, e.g. for pressure driven secondary flows, turbine nozzle wakes, turbulent boundary layers. The formulation's modeling of blade surface heat transfer is assessed. The numerical model is used to investigate the structure of phenomena associated with tip clearance flows in a turbine nozzle. A SOLUTION ALGORITHM FOR THE PREDICTION OF COMPRESSIBLE LAMINAR AND TURBULENT SHEAR FLOWS Ph.D. Thesis
Murali Beddhu 1992 124 p
Avail: Univ. Microfilms Order No. DA9312038

An implicit, finite volume code was developed for solving the complete set of three dimensional compressible Navier-Stokes equations for both laminar and turbulent cases to study separated flows with or without turbulence. For turbulent flows, mass weighted averaged equations for the mean flow along with a two equation (kappa-epsilon) closure are used. The governing equations are cast in general, time dependent curvilinear coordinates. First, the mean flow equations are solved using a fractional time stepping algorithm and then the equations for kappa and epsilon are solved separately using a modified two pass scheme at each time step. The fractional time stepping algorithm solves the convective and pressure terms only during the first fraction of the time step and then corrects this field in the second fraction by solving the viscous and turbulent terms. Integration through the first fraction of the time step is performed by an implicit Euler code that uses modified two pass scheme with Roe's flux difference splitting on the right hand side and flux vector splitting on the left hand side. Integration through the second fraction of the time step is performed using the Thomas algorithm, after casting the governing equations to yield a tridiagonal system. Numerous results for a wide range of Reynolds numbers and Mach numbers and with different geometries were obtained to test the validity of the code. Laminar channel flow at M(sub infinity) = 0.3 and Re(sub infinity) = 300 with both adiabatic wall and constant wall temperatures were obtained. Solutions for the channel flow and for the flow over an impulsively started flat plate at various wall temperatures agree very well with exact analytical solutions. Separated flow over a backward facing step at M(sub infinity) = 0.3 and Re(sub infinity) = 300 agrees well with experiments. Laminar flow over a waisted (contoured) axisymmetric body at M(sub infinity) = 1.39 and Re(sub infinity) = 5.04 x 10(exp 6) and over a bump on the floor of a wind tunnel at M(sub infinity) = 0.14 and Re(sub infinity) = 10800 are also presented and compared with other experiments and computations. Turbulent solutions obtained for a channel flow at M(sub infinity) = 0.3 and Re = 1.0xe(sup 6) were shown to agree well with other numerical results. These solutions are obtained using the kappa-epsilon equations with a modified near wall effect term in the epsilon equation. Dissert. Abstr.

EXPERIMENTAL MEASUREMENT OF LOCAL HEAT TRANSFER COEFFICIENTS OVER DISCRETE ROUGHENED PLATES USING INFRARED THERMOGRAPHY Ph.D. Thesis
David Alfredo Aliaga 1992 268 p
Avail: Univ. Microfilms Order No. DA9309114

Convective heat transfer over ribbed surfaces is a very complex process that requires detailed measurements for further understanding. Recent developments in infrared detector designs, optical attachments and computer and video capabilities have produced accurate infrared thermography systems with the spatial resolution required to obtain local heat transfer measurements on surfaces of complex geometry. Thus infrared thermography represents an attractive alternative to existing methods for heat transfer measurements (i.e. thermocouples, naphthalene sublimation, or liquid crystal measurements). The present investigation describes a new experimental method which uses infrared thermography in a subsonic wind tunnel to obtain detailed temperature measurements over ribbed plates with constant heat flux. The infrared system used in this study incorporated an infrared detector with a closed cycle microcooler which permitted the infrared camera to be positioned at arbitrary viewing angles. This flexibility permitted direct observations of the ribbed surface without the use of reflective optics that would have increased the inaccuracy of the procedure. Reference thermocouples placed at strategic locations over the ribbed plates were used to correct temperature readings of the infrared system in order to minimize measurement errors. Three ribbed plates were tested. Plates A and B had ribs of square cross section. The rib spacing (pitch) on plate A was designed so that regions of separation and reattachment would occur on the plate between ribs whereas plate B was designed to produce only regions of separation and recirculation. Plate C was constructed as an improved version of plate A and included trapezoidal ribs. The rib height and pitch on plate C was the same as on plate A. The trapezoidal shape of the rib for plate C was designed to minimize the recirculation regions in the front and back of the ribs while allowing reattachment at the base surface of the plate. Local heat transfer coefficients surrounding the ribs are presented and comparisons between plates are drawn. It is shown that the new method of heat transfer measurement is able to detect numerous small scale features of the complex flow field and consequent heat transfer distribution around ribs of arbitrary shape. Dissert. Abstr.

FLOW LIMITATION AND FLUTTER IN MEMBRANE WALLED COLLAPSIBLE TUBES: A MODEL FOR EXPIRATORY WHEEZING Ph.D. Thesis
Colin Walsh 1992 291 p
(ISBN-0-315-73875-8) Avail: Univ. Microfilms Order No. DANN73875

During forced expiration from a full lung, the flow are limits due to collapse of the central airways. This is accompanied by audible wheezes, which are attributed to flow-induced oscillation of the collapsed airway wall. Mechanical and theoretical models of such physiological phenomena are referred to as 'collapsible tubes'. Most studies consider flow in rubber tubes where the collapse is complex. Thus, corresponding one dimensional (1-D) nonlinear theories rely on ad hoc structural models. The central airways have stiff anterior and lateral walls and a compliant posterior membrane suggesting simplified models. Experiments use a rectangular trough closed by a latex sheet. The oscillations involve three modes: weak low and intermediate frequency modes and a strong high frequency one. There is nonlinear interaction between the low and high frequency modes and the intermediate and high frequency ones are insensitive to the downstream flow properties. An axisymmetric annular geometry retains important experimental features and simplifies the current analysis. The nonlinear equations assume a shallowness condition and it is shown that normal inertia is negligible while axial inertia remains significant for the conditions in our experiments. Thus, the pressure drop across the wall is a static function of the local wall geometry: a generalized tube law. Numerical solutions display flutter for which axial tension is strongly stabilizing. The energy transfer from the mean flow depends on both the wall inertia and on variations in the axial tension due to variations in the axial stretch, mediated by compound wall curvature. Nonlinear effects modify the flutter, but the available mechanisms are normally unable to limit the growth. However, stable large amplitude oscillations can occur, and spectral analysis reveals three modes that have the qualitative properties of the experimental ones. However, there is extra harmonic structure and the intermediate frequency mode continues to grow disrupting any large amplitude oscillations that do develop. No other 1-D unsteady formulation considers wall inertia, compound curvature, or axial motion. Further, the qualitative agreement between the new experimental and numerical results suggests that these features may be significant and that the annular geometry is a useful model for studying the stability collapsible tube flows. Dissert. Abstr.

STUDIES OF TURBULENT SHEAR FLOWS AND THEIR CONTROL Final Report, 22 Feb. 1989 - 17 Oct. 1992
Joseph T. C. Liu 17 Oct. 1992 5 p
(Grant NAG3-1016)
(NASA-CR-194114; NAS 1.26:194114) Avail: CASI HC A01/MF A01

The intent of the original proposal and the work carried out under the grant was to explore the instabilities of turbulent free shear flows of an incompressible fluid. The purpose for doing so was that coherent instabilities are susceptible to control via upstream forcing and because at sufficient finite amplitudes, the coherent modes enter into nonlinear interactions with the mean motion and thus, through such nonlinear interactions, the control of mixing and of mean flow spreading can be effected through the control of the coherent structures. A CONTROL VOLUME FINITE ELEMENT METHOD FOR THREE-DIMENSIONAL, INCOMPRESSIBLE, VISCOUS FLUID FLOW Ph.D. Thesis
Helmut John Saabas 1991 442 p
(ISBN-0-315-72019-0) Avail: Univ. Microfilms Order No. DANN72019

An equal-order co-located Control Volume Finite Element Method (CVFEM) for the prediction of multidimensional, incompressible, viscous fluid flow problems were formulated. CVFEM's provide the geometric flexibility traditionally associated with finite element methods. In addition, their control volume based formulation facilitates physically meaningful interpretation of the resulting discretization equations. In the proposed CVFEM, the calculation domain is divided into three-node triangular and four-node tetrahedral finite elements in two and three-dimensions, respectively. Each element is further subdivided in such a way that upon assembly of all elements, complete control volumes are formed about each node in the calculation domain. Interpolation functions for the dependent variables are prescribed in a manner that is consistent with the physical process they are intended to approximate. In this context, three different interpolation schemes of the convective flux across control volume surfaces are investigated, one of which guarantees positive contributions to the coefficients in the algebraic discretization equations. Appropriate conservation laws are imposed on the control volumes associated with the nodes. The resulting sets of integral conservation equations are then approximated by algebraic discretization equations, using the previously-mentioned interpolation functions. These nonlinear, coupled, algebraic equations are solved by a sequential solution procedure which incorporates Picard iterations. The proposed method was implemented into computer programs, and used to solve several test problems. These include convection-diffusion problems, and laminar and turbulent flow problems, in both two- and three-dimensions. The results demonstrate the ability of the proposed CVFEM to accurately solve the mathematical model used. Lastly, the CVFEM was used to predict flows similar to those found in film cooled gas turbine aerofoils. A complementary experimental program was designed and set up to investigate such flows. The numerical predictions were compared to the experimental observations of mean velocities, normal turbulent stresses, and one component of the turbulent shear stress. These comparisons indicated that the high Reynolds number Kappa-Epsilon turbulence model used is unable to capture certain features of the flow. It appears as if a low-Reynolds number turbulence model, with appropriate modifications to account for streamline curvature and non-isotropy of the turbulence in the vicinity of the walls, would be better suited to the prediction of such flows. This new model can be easily incorporated into the CVFEM proposed. Dissert. Abstr.

STUDIES OF MOMENTUM AND ENERGY TRANSFER ACROSS WAVY GAS-LIQUID INTERFACES Final Report
A. E. Dukler 1 Jun. 1993 67 p

(Contract N00014-90-J-1090)
(AD-A266432) Avail: CASI HC A04/MF A01

Two phase gas-liquid flow and its associated interfaces exist in a wide variety of situations of importance to the Navy and this has prompted the study of the basic flow mechanics which underlie this complex process. The existence of wind-wave interactions over large bodies of water have long been recognized as a special case of two phase flow where the presence of the deformable interface plays a complex role in the generation of waves due to the action of the wind. Less well recognized, but of great importance, are situations of two phase flow which are found in component of power systems such as condensers, boiler refrigeration loops, and cryogen lines. Here the characteristics of two phase flow are critical to the reliable design and safe operation of such systems. DTIC

DEVELOPMENT OF A RECURSION RNG-BASED TURBULENCE MODEL
Ye Zhou, George Vahala, and S. Thangam Washington Aug. 1993 31 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191511; ICASE-93-51; NAS 1.26:191511) Avail: CASI HC A03/MF A01

Reynolds stress closure models based on the recursion renormalization group theory are developed for the prediction of turbulent separated flows. The proposed model uses a finite wavenumber truncation scheme to account for the spectral distribution of energy. In particular, the model incorporates effects of both local and nonlocal interactions. The nonlocal interactions are shown to yield a contribution identical to that from the epsilon-renormalization group (RNG), while the local interactions introduce higher order dispersive effects. A formal analysis of the model is presented and its ability to accurately predict separated flows is analyzed from a combined theoretical and computational stand point. Turbulent flow past a backward facing step is chosen as a test case and the results obtained based on detailed computations demonstrate that the proposed recursion -RNG model with finite cut-off wavenumber can yield very good predictions for the backstep problem. EVOLUTION OF DISTURBANCES IN STAGNATION POINT FLOW Final Report
William O. Criminale (Washington Univ., Seattle.), Thomas L. Jackson (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.), and D. Glenn Lasseigne (Old Dominion Univ., Norfolk, VA.) Washington Aug. 1993 25 p Submitted for publication
(Contract NAS1-19480; AF-AFOSR-0180-91; RTOP 505-90-52-01)
(NASA-CR-191516; NAS 1.26:191516; ICASE-93-56) Avail: CASI HC A03/MF A01

The evolution of three-dimensional disturbances in an incompressible three-dimensional stagnation-point flow in an inviscid fluid is investigated. Since it is not possible to apply classical normal mode analysis to the disturbance equations for the fully three-dimensional stagnation-point flow to obtain solutions, an initial-value problem is solved instead. The evolution of the disturbances provide the necessary information to determine stability and indeed the complete transient as well. It is found that when considering the disturbance energy, the planar stagnation-point flow, which is independent of one of the transverse coordinates, represents a neutrally stable flow whereas the fully three-dimensional flow is either stable or unstable, depending on whether the flow is away from or towards the stagnation point in the transverse direction that is neglected in the planar stagnation point. HIGH FLUX HEAT EXCHANGER Interim Report, 1 Oct. 1990 - 29 Oct. 1991
Edward M. Flynn and Michael J. Mackowski Jan. 1993 49 p
(Contract F33615-90-C-2054)
(AD-A266341; WL-TR-93-2027) Avail: CASI HC A03/MF A01

This interim report documents the results of the first two phases of a four-phase program to develop a high flux heat exchanger for cooling future high performance aircraft electronics. Phase 1 defines future needs for high flux heat removal in advanced military electronics systems. The results are sorted by broad application categories: (1) commercial digital systems, (2) military data processors, (3) power processors, and (4) radar and optical systems. For applications expected to be fielded in five to ten years, the outlook is for steady state flux levels of 30-50 W/sq cm for digital processors and several hundred W/sq cm for power control applications. In Phase 1, a trade study was conducted on emerging cooling technologies which could remove a steady state chip heat flux of 100 W/sq cm while holding chip junction temperature to 90 C. Constraints imposed on heat exchanger design, in order to reflect operation in a fighter aircraft environment, included a practical lower limit on coolant supply temperature, the preference for a nontoxic, nonflammable, and nonfreezing coolant, the need to minimize weight and volume, and operation in an accelerating environment. The trade study recommended the Compact High Intensity Cooler (CHIC) for design, fabrication, and test in the final two phases of this program. DTIC

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF BLOWING RATIO PARAMETER ON HEAT TRANSFER TO A FILM-COOLED FLAT PLATE M.S. Thesis
Marco R. Valencia Jun. 1993 182 p
(AD-A266599; AFIT/GAE/ENY/93J-01) Avail: CASI HC A09/MF A02

The effects of blowing ratio on film cooling effectiveness were investigated. Two round-nosed test plates were used, one made of aluminum and the second of corian (low thermal conductivity). Injection at 35 degrees in the downstream direction was studied. Helium was mixed with air to produce a density ratio (coolant to mainstream) of 1.6 and 2.0, while the blowing ratio varied from 0.3 to 2.2. Surface temperature was measured by thin film gages located up to a nondimensional downstream distance X/D of 30. Two injection regimes, weak and strong, were found. In the weak regime, film cooling reduced gage heat flux at all thin film gage locations, however, film cooling was more effective for X/D less than 10. In the strong regime, the effectiveness of film cooling for X/D less than 10 was greatly reduced. Maximum film cooling effectiveness occurred between the weak and strong regime at a blowing ratio of 1.0. Changing the density ratio from 1.6 to 2.0 varied the measured gage heat flux less than 5 percent. Gage heat flux was correlated by the velocity ratio scaling parameter (X/D)VR to the -4/3 in both injection regimes. Gage heat flux with no film cooling, assuming a turbulence level of 10 percent, deviated less than 8 percent from theoretical results using the corian plate and less than 10 percent using the aluminum plate. ON THE SECONDARY INSTABILITY OF THE MOST DANGEROUS GOERTLER VORTEX Final Report
S. R. Otto and James P. Denier (New South Wales Univ., Kensington, Australia.) Washington Jul. 1993 14 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191504; ICASE-93-46; NAS 1.26:191504) Avail: CASI HC A03/MF A01

Recent studies have demonstrated the most unstable Goertler vortex mode is found in flows, both two and three-dimensional, with regions of (moderately) large body curvature and these modes reside within a thin layer situated at the base of the conventional boundary layer. Further work concerning the nonlinear development of the most dangerous mode demonstrates that the flow results in a self induced flow reversal. However, prior to the point at which flow reversal is encountered, the total streamwise velocity profile is found to be highly inflectional in nature. Previous work then suggests that the nonlinear vortex state will become unstable to secondary, inviscid, Rayleigh wave instabilities prior to the point of flow reversal. Our concern is with the secondary instability of the nonlinear vortex states, which result from the streamwise evolution of the most unstable Goertler vortex mode, with the aim of determining whether such modes can induce a transition to a fully turbulent state before separation is encountered. STABILITY OF OSCILLATORY TWO PHASE COUETTE FLOW Final Report

Adrian V. Coward (Manchester Univ., England.) and Demetrios T. Papageorgiou (New Jersey Inst. of Tech., Newark.) Jul. 1993 29 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191501; ICASE-93-43; NAS 1.26:191501) Avail: CASI HC A03/MF A01

We investigate the stability of two phase Couette flow of different liquids bounded between plane parallel plates. One of the plates has a time dependent velocity in its own plane, which is composed of a constant steady part and a time harmonic component. In the absence of time harmonic modulations, the flow can be unstable to an interfacial instability if the viscosities are different and the more viscous fluid occupies the thinner of the two layers. Using Floquet theory, we show analytically in the limit of long waves, that time periodic modulations in the basic flow can have a significant influence on flow stability. In particular, flows which are otherwise unstable for extensive ranges of viscosity ratios, can be stabilized completely by the inclusion of background modulations, a finding that can have useful consequences in many practical applications. NUMERICAL INVESTIGATIONS IN THREE-DIMENSIONAL INTERNAL FLOWS Semiannual Status Report, 1 Jan. - 30 Jun. 1993
William C. Rose 1993 31 p
(Contract NCC2-507)
(NASA-CR-194143; NAS 1.26:194143) Avail: CASI HC A03/MF A01

In the present reporting period, the 3D STUFF code was used to solve the underbody flow for the waverider configuration vehicle. In order to start the space-marched version of the code, the time-marched version (TUFF) was used to solve the forward portion of the underside of the forebody flowfield. A grid was generated which went from the tip of the nose to the location of the cowl lip. This includes all of the inlet ramp system. Previous indications were that three-dimensional effects could be expected on the ramps of such an aircraft. For purposes of the present study, no sidewalls were assumed. The sidewalls were eliminated to simplify the calculations and to show the potential effects of three-dimensional flow in the absence of a full sidewall. Further, this flow was also analyzed using the newly released OVERFLOW code and comparisons between the two codes were made. In addition to these 3D calculations, 2D calculations using the OVERFLOW code were also obtained for the Mach 5 inlet model in this reporting period. Comparisons between the experimental data, previous computational fluid dynamics (CFD) results and those from OVERFLOW were made. Author (revised)

POTENTIAL FLOW IN IN-LINE AND STAGGERED TUBE BANKS
S. B. Beale Feb. 1993 54 p
(IME-CRE-TR-006; NRC-36183; CTN-93-60836) Avail: CASI HC A04/MF A01

An analytical solution for the potential flow in in-line and staggered banks of tubes is derived using complex variable theory. The complex potential is written as a power series in terms of displacement. Series coefficients are provided for in-line square, rotated square, and equilateral triangle tube banks with pitch to diameter ratios in the range of 1.05:1 to 100:1. Contour plots of velocity potential, streamlines, and pressure, together with graphs of velocity and pressure around the cylinder diameter and across the minimum cross section, are illustrated for typical tube bank arrangements. A listing of the computer program that generates tables of coefficients as well as pressure and velocity data is appended. CISTI

SLOSHING DYNAMICS ON ROTATING HELIUM DEWAR TANK Final Report
R. J. Hung Sep. 1993 66 p
(Grant NAG8-129)
(NASA-CR-194403; NAS 1.26:194403) Avail: CASI HC A04/MF A01

The generalized mathematical formulation of sloshing dynamics for partially filled liquid of cryogenic superfluid helium II in dewar containers driven by both the gravity gradient and jitter accelerations applicable to scientific spacecraft which is eligible to carry out spinning motion and/or slew motion for the purpose to perform scientific observation during the normal spacecraft operation are investigated. An example is given with Gravity Probe-B (GP-B) spacecraft which is responsible for the sloshing dynamics. The jitter accelerations include slew motion, spinning motion, atmospheric drag on the spacecraft, spacecraft attitude motions arising from machinery vibrations, thruster firing, pointing control of spacecraft, crew motion, etc. Explicit mathematical expressions to cover these forces acting on the spacecraft fluid systems are derived. The numerical computation of sloshing dynamics were based on the non-inertia frame spacecraft bound coordinate, and solve time dependent, three-dimensional formulations of partial differential equations subject to initial and boundary conditions. The explicit mathematical expressions of boundary conditions to cover capillary force effect on the liquid vapor interface in microgravity environments are also derived. The formulations of fluid moment and angular moment fluctuations in fluid profiles induced by the sloshing dynamics, together with fluid stress and moment fluctuations exerted on the spacecraft dewar containers were derived. Results were widely published in the open journals. Author (revised)

THE SPECTRAL VISCOSITY METHOD APPLIED TO SIMULATION OF WAVES IN A STRATIFIED ATMOSPHERE
Oeyvind Andreassen, Ivar Lie, and Carl Erik Wasberg 15 Dec. 1992 45 p
(FFI-92/7047; ETN-93-94452) Avail: CASI HC A03/MF A01

A spectral collocation method is used to solve an atmospheric gravity wave simulation problem. It is modeled by the nonlinear, inviscid, two dimensional Euler equations including gravity. The nonlinear transfer of energy to higher frequencies destroys the long time calculations if no method is applied for this purpose. Implementation aspects, effects on the resulting system of ordinary differential equations, tuning of parameters, and evaluation of results are discussed. An implementation that works well for larger simulations is found. Guidelines for the application of the method are given. ESA

Turbulent particle dispersion, a dominant transport phenomena in gas turbine combustion chambers, is investigated by numerical simulations. A physical model is evaluated using results from a model experiment. Besides averaged transport parameters the instantaneous transport phenomena are analyzed for monosized droplets in swirling flows relevant for gas turbine combustion chambers. A good agreement between measured and calculated data can be stated. A parameter variation evidences the impact of the detailed description of the characteristics of gas turbulence. A simulation procedure is established for promotion in solving the engineering problem of the design of gas turbine combustion chambers. ESA

THE METHOD OF LAPLACE TRANSFORM MULTIQUADRICS (LTMQ) FOR THE SOLUTION OF THE GROUNDWATER FLOW EQUATION
G. J. Moridis and E. Kansa (California Univ., Livermore. Lawrence Livermore Lab.) Jun. 1992 7 p Presented at the 7th International Association for Mathematics and Computers in Simulation Conference on Computer Methods for Partial Differential Equations, New Brunswick, NJ, 22-24 Jun. 1993
(Contract DE-AC03-76SF-00098)
(DE93-010408; LBL-32529; CONF-9306153-1) Avail: CASI HC A02/MF A01

This paper presents a new numerical method, the Laplace Transform MultiQuadrics (LTMQ) method, developed for the solution of the diffusion-type parabolic Partial Differential Equation (PDE) of fluid flow through porous media. LTMQ combines a MultiQuadrics (MQ) approximation scheme with a Laplace transform formulation. The use of MQ in the spatial approximations allows the accurate description of problems in complex porous media with a very limited number of nodes. The Laplace transform

formulation eliminates the need for time discretization, thus allowing an unlimited time step size without any loss of accuracy. LTMQ is tested against results from three test problems of groundwater flow obtained from a standard Finite Difference (FD) model, as well as from analytical solutions. An excellent agreement between the LTMQ and the analytical and FD solutions is observed, while significant reductions in computer execution times may be achieved. DOE

DESIGN AND EVALUATION OF SINGLE AND DUAL FLOW THRUST VECTOR NOZZLES WITH POST EXIT VANES Semiannual Progress Report, Jun. - Dec. 1992
Thomas W. Carpenter, Stephen E. Vaccarezza, and Sean Dobbins 1992 35 p Original contains color illustrations
(Contract NCC2-748)
(NASA-CR-193393; NAS 1.26:193393) Avail: CASI HC A03/MF A01; 12 functional color pages

This Thrust Vectored Research project required that a 1/24 scale model of the F/A-18 High Alpha Research Vehicle, (HARV), propulsion system be constructed on the university campus. This propulsion system was designed for cold flow testing on a multicomponent test rig. Forces and moments were measured to study nozzle performance parameters. The flow visualization technique of color Schlieren photography was performed to investigate the flow phenomena at the nozzle exit. The flow interactions that were identified consisted of vane nozzleing between the outer and lower vanes and vane tip interference. The thrust vectoring system consisted of three asymmetrically spaced vanes installed circumferentially on a maximum afterburner nozzle. The performance of the nozzle was investigated with the outer and lower vanes equally deflected, (-10 deg is less than delta(sub v) is less than 25 deg), and with the upper vane fully retracted, (delta(sub v) equals -10 deg). The nozzle pressure ratio ranged from 4 to 6. The results indicated that a vane nozzleing effect developed at nozzle pressure ratios of 4 and 6 when the outer and lower vanes were deflected far enough into the flow field such that the increase in vane area accelerated the flow past the vanes causing distorted shock waves. This accelerated flow was a result of a pressure differential existing between the inside surface of the vane and the ambient pressure. The stagnation pressure that developed along the inside surface of the vane accelerated the flow past the vanes causing it to equalize with ambient pressure, thus providing distorted shock waves. A tip interference was present at the trailing edge of the upper vane as a result of low nozzle pressure, NPR 4, with high vane deflection, delta(sub v) equals 25 degrees, and also with a high nozzle pressure, NPR 6, and low vane deflections, delta(sub v) equals 15 degrees. THE ACCURACY OF APPROXIMATING RADIATIVE HEAT TRANSFER USING A TEMPERATURE DEPENDENT THERMAL CONDUCTIVITY
J. R. Creighton 11 Feb. 1993 25 p
(Contract W-7405-eng-48)
(DE93-013105; UCRL-ID-113019) Avail: CASI HC A03/MF A01

Radiative heat transfer across the gap between two coaxial cylinders can be approximated using an equivalent thermal conductivity that is a cubic polynomial in the temperatures T(sub 1) and T(sub 2) of the two surfaces (T(sub 1) greater than T(sub 2)). It is convenient to write the polynomial in terms of the average temperature, yielding T(sub avg(exp 3)) multiplied by an expression in T(sub avg)/T(sub 1). This expression has a value close to unity when the temperature difference is small and approaches 2 as the lower temperature approaches zero. The approximation is valid if the temperature of each surface is uniform. Numerical calculations showed that it is also reasonably accurate when the temperature varies with height on the cooler surface. An electrical circuit analogy shows that this should be generally true, but that the approximation may be poor when the hotter surface temperature is not uniform. The appendix shows the derivation of the view factors used in the radiative heat transport calculations. DOE

BOAST 2 simulates isothermal, darcy flow in three dimensions. It assumes that reservoir liquids can be described in three fluid phases (oil, gas, and water) of constant composition, with physical properties that depend on pressure, only. These reservoir fluid approximations are acceptable for a large percentage of the world's oil and gas reservoirs. Consequently, BOAST 2 has a wide range of applicability. BOAST 2 can simulate oil and/or gas recovery by fluid expansion, displacement, gravity drainage, and capillary imhibition mechanisms. Typical field production problems that BOAST 2 can handle include primary depletion studies, pressure maintenance by water and/or gas injection, and evaluation of secondary recovery waterflooding and displacement operations. Technically, BOAST 2 is a finite, implicit pressure, explicit saturation (IMPES) numerical simulator. It applies both direct and iterative solution techniques for solving systems of algebraic equations. The well model allows specification of rate or pressure constraints on well performance, and the user is free to add or to recomplete wells during the simulation. In addition, the user can define multiple rock and PVT regions and can choose from three aquifer models. BOAST 2 also provides flexible initialization, a bubble-point tracking scheme, automatic time-step control, and a material balance check on solution stability. The user controls output, which includes a run summary and line-printer plots of fieldwide performance. DOE

MULTIGRID SOLUTION OF INTERNAL FLOWS USING UNSTRUCTURED SOLUTION ADAPTIVE MESHES Final Report
Wayne A. Smith and Kenneth R. Blake Nov. 1992 37 p
(Contract NAS3-25785; SBIR-01.01-3800)
(NASA-CR-194233; NAS 1.26:194233; TN-035) Avail: CASI HC A03/MF A01

This is the final report of the NASA Lewis SBIR Phase 2 Contract Number NAS3-25785, Multigrid Solution of Internal Flows Using Unstructured Solution Adaptive Meshes. The objective of this project, as described in the Statement of Work, is to develop and deliver to NASA a general three-dimensional Navier-Stokes code using unstructured solution-adaptive meshes for accuracy and multigrid techniques for convergence acceleration. The code will primarily be applied, but not necessarily limited, to high speed internal flows in turbomachinery. Derived from text

AN ADAPTIVE PROJECTION METHOD FOR THE INCOMPRESSIBLE EULER EQUATIONS
A. S. Almgren, J. B. Bell, L. H. Howell, and P. Colella (California Univ., Berkeley.) Jun. 1993 10 p Presented at the 11th International Computational Fluid Dynamics Conference, 28th Thermophysics Conference and 23rd Fluid Dynamics, Plasma Dynamics and Laser Conference, Orlando, FL, 5-7 Jul. 1993
(Contracts W-7405-eng-48; DE-FG03-92ER-25140)
(DE93-016428; UCRL-JC-113853; CONF-930714-2) Avail: CASI HC A02/MF A01

We present a method for solving the time-dependent incompressible Euler equations on an adaptive grid. The method is based on a projection formulation in which we first solve convection equations to predict intermediate velocities, and then project these velocities onto a space of approximately divergence-free vector fields. Our treatment of the convection step uses a specialized second-order upwind method for differencing the nonlinear convection terms that provides a robust treatment of these terms suitable for inviscid flow. Our approach to adaptive refinement uses a nested hierarchy of grids with simultaneous refinement of the grids in both space and time. The integration algorithm on the grid hierarchy is a recursive procedure in which a coarse grid is advanced; fine grids are advanced multiple steps to reach the same time as the coarse grid and the grids are then synchronized. We will describe the integration algorithm in detail, with emphasis on the projection used to enforce the incompressibility constraint. Numerical examples are presented to demonstrate the convergence properties of the method and to illustrate the behavior of the method at the interface between coarse and fine grids. An additional example demonstrates the performance of the method on a more realistic problem. DOE

TURBULENT DIFFUSION IN HOMOGENEOUS SHEAR FLOW WITH STABLE DENSITY STRATIFICATION Ph.D. Thesis - Tech. Univ. Munich [TURBULENTE DIFFUSION IN EINER HOMOGENEN SCHERSTROEMUNG MIT STABILER DICHTESCHICHTUNG]
Hans-Jakob Kaltenbach Aug. 1992 157 p In GERMAN
(DLR-FB-92-26; ETN-93-9395763) Avail: CASI HC A08/MF A02

The mixing properties of homogeneous turbulent flows, which are influenced by stable density stratification and mean shear, are investigated using direct numerical simulation and large eddy simulation. The dependency of the components of the turbulence diffusivity tensor on the value of the Gradient Richardson number is demonstrated. Stable stratification reduces the vertical transport of species stronger than the horizontal transport. In cases with strong background stratification the Froude number plays an important role besides the Richardson number. Little different is found between direct simulation and large eddy simulation results. Both types of simulations are concluded to refer to the same order of magnitude of the Reynolds number. The results are sensitive to the value of the Prandtl number in cases with Richardson number greater than 0.25. ESA

A CONDUCTION MODEL FOR THE VACUUM ARC REMELTING PROCESS
D. H. Ferriss Apr. 1993 18 p
(NPL-DMM(A)-98; ETN-93-94606) Copyright Avail: Issuing Activity (National Physical Laboratory, Teddington, Middlesex TW11 0LW, United Kingdom)

Equations describing the time dependent heat transfer by conduction during the vacuum arc remelting process are presented. The model is assumed axisymmetric and allows for latent heat effects using a simple enthalpy formulation. Boundary conditions allow for various modes of surface heat transfer including the combination of radiation effects and heat transfer coefficients. Scaling of the equations identifies various non dimensional parameters characterizing the problem solution. The results of a specimen calculation are presented. ESA

COLLISIONS AND SEPARATIONS IN 2D HYDRODYNAMICAL CODE M.S. Thesis
Shimon Asida Jun. 1991 106 p In HEBREW
(ITN-93-85225) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

Hydrodynamic problems involving the collision or separation of zones of different materials include the following types: armor penetration by a jet formed in the explosion of a shaped charge or by a kinetic projectile, and instabilities in cosmic jets. Calculations of hydrodynamic processes are based on numerical simulations which solve the differential equations by means of difference equations. A special grid is defined and the physical system is advanced via finite steps in time; in a Eulerian treatment, the grid is stationary in space whereas in a Lagrangian treatment it moves together with the fluid. In Lagrangian methods, the grid is defined on the fluid and the boundaries between materials are formed by the edges of computational cells, so that the shape of the grid depends on the shape of the boundary. Where there is a strong flow, the cells distort and the grid must be frequently redefined to enable the calculation to continue. Boundary collisions cause difficulty in defining a grid. In Eulerian methods, where the computational grid is defined over all the space through which the materials flow, it is necessary to use cells with non-homogeneous contents to follow the boundaries; such calculations are more complicated and less accurate. The aim of the present work was to develop a Lagrangian method for treating such collisions. The code, based on an existing 2D Lagrangian code with the addition of a new collision mechanism, uses a mixed computational grid, comprising squares and triangles, with which it is possible to describe systems. A VERTEX-BASED FINITE-VOLUME ALGORITHM FOR THE NAVIER-STOKES EQUATIONS
S. K. Chakrabartty and K. Dhanalakshmi *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 1-7 (For primary document see N94-14598 02-34)
Avail: CASI HC A02/MF A03

A vertex-based, finite-volume algorithm has been developed to solve the Reynolds-averaged Navier-Stokes equations without thin-layer approximation. An explicit, five-stage Runge-Kutta, time-stepping scheme has been used for time integration along with different acceleration techniques to reach the steady state. A code employing multi-block grid structure has been developed. This code can accept any type of grid topology. As test cases, the turbulent flow past RAE-2822 and NACA-0012 airfoils, and the laminar flow past a cropped delta wing at ten degrees angle of attack have been computed and the results compared with available numerical and experimental results. The Baldwin-Lomax turbulence model has been used in the case of turbulent flows. Author

THE STRUCTURE OF LAMINAR FLOW IN A THREE-DIMENSIONAL DRIVEN CAVITY

M. D. Deshpande and P. N. Shankar *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 25-36 (For primary document see N94-14598 02-34)

Avail: CASI HC A02/MF A03

We present some details of the steady laminar flow fields that are generated in a fluid filled cavity by the motion of one of the faces. The flow fields have been obtained by the numerical solution of the Navier-Stokes equations in the Reynolds number range 0 less than Re less than or equal to 1000. The streamline patterns clearly indicate the very complicated nature of the eddy structures and their dependence on Reynolds number. Further work is currently in progress to extend the computations to higher Reynolds numbers in order that transition and turbulence in the cavity may be studied. Author (revised)

A VORTEX METHOD FOR VISCOUS UNSTEADY FLOWS

P. K. Dutta *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 37-50 (For primary document see N94-14598 02-34)

Avail: CASI HC A03/MF A03

A simple method is presented for the creation of vorticity from a solid boundary in the form of discrete vortex blobs. These vortices have uniform-vorticity cores and are released from a number of points distributed around the body surface at a small distance away from the surface. Their strengths are obtained by satisfying the no-slip condition at the midpoints of the corresponding vortex sheets. The dynamics of these vortices is then considered by including the effect of viscous diffusion by random walk approach. The method is applied to the starting flow past a circular cylinder. A detailed parametric study shows that viscosity has the most significant effect on the computed results and, in order to obtain meaningful results, it must be reduced suitably to compensate for the artificial viscosity arising from numerical integration of equations of motion of the discrete vortices. Results are obtained for three typical Reynolds numbers of 9500, 3000 and 550, and are found to be in very good agreement with experimental measurements for the centerline velocity distribution. In particular, the case of Re = 550 illustrates the usefulness of the present model even at low Reynolds numbers. The vortex patterns, velocity vectors and particle path lines also conform to the experimental flow visualization pictures. Though the method is developed for a simple configuration like a circular cylinder, it can be easily extended to any general body shape. Author

AN IMPLICIT FINITE VOLUME NODAL POINT SCHEME FOR THE SOLUTION OF TWO-DIMENSIONAL COMPRESSIBLE NAVIER-STOKES EQUATIONS

Vimala Dutta *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 51-59 (For primary document see N94-14598 02-34)

Avail: CASI HC A02/MF A03

An implicit finite volume nodal point scheme has been developed for solving the two-dimensional compressible Navier-Stokes equations. The numerical scheme is evolved by efficiently combining the basic ideas of the implicit finite-difference scheme of Beam and Warming (1978) with those of nodal point schemes due to Hall (1985) and Ni (1982). The 2-D Navier-Stokes solver is implemented for steady, laminar/turbulent flows past airfoils by using C-type grids. Turbulence closure is achieved by employing the algebraic eddy-viscosity model of Baldwin and Lomax (1978). Results are presented for the NACA-0012 and RAE-2822 airfoil sections. Comparison of the aerodynamic coefficients with experimental results for the different test cases presented here establishes the validity and efficiency of the method. Author

STABILITY OF SPATIALLY DEVELOPING BOUNDARY LAYERS

Rama Govindarajan *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 69-76 (For primary document see N94-14598 02-34)

Avail: CASI HC A02/MF A03

A new formulation of the stability of boundary-layer flows in pressure gradients is presented, taking into account the spatial development of the flow. The formulation assumes that disturbance wavelength and eigenfunction vary downstream no more rapidly than the boundary-layer thickness, and includes all terms of O(1) and O(R(exp -1)) in the boundary-layer Reynolds number R. Although containing the Orr-Sommerfeld operator, the present approach does not yield the Orr-Sommerfeld equation in any rational limit. In Blasius flow, the present stability equation is consistent with that of Bertolotti et al. (1992) to terms of O(R(exp -1)). For the Falkner-Skan similarity solutions neutral boundaries are computed without the necessity of having to march in space. Results show that the effects of spatial growth are striking in flows subjected to adverse pressure gradients.

A FINITE VOLUME METHOD FOR COMPUTATION OF VISCOUS FLOW IN COMPLEX CONFIGURATIONS

Sekhar Majumdar *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 91-114 (For primary document see N94-14598 02-34)

Avail: CASI HC A03/MF A03

A calculation procedure is presented for computation of steady, recirculating viscous flows in complex configurations. The algorithm has been developed for non-orthogonal coordinate systems using collocated variable arrangement. In order to handle both incompressible and compressible flows, pressure has been selected as a primary dependent variable in preference to density. The pressure field is evaluated using the pressure-velocity correction strategy of the SIMPLE algorithm, suitably modified for collocated variable arrangement. The capability of the

three-dimensional version of the algorithm has been demonstrated for prediction of two incompressible laminar flow situations with complex geometry. Author

A GRID GENERATION PACKAGE FOR HIGH ASPECT RATIO WINGS **c02**

J. S. Mathur and S. K. Chakrabartty *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 115-121 (For primary document see N94-14598 02-34)

Avail: CASI HC A02/MF A03

A grid generation package has been developed to generate a quasi-three-dimensional grid of either O-H or C-H topology. Grid stacking has been implemented here to use two dimensional grid generation routines at different span stations, and then stack these together to get a three-dimensional grid. An algebraic grid generation routine for C-type grid with all the flexibilities of grid stretching and an elliptic grid generation routine with control functions for O-type grid have been used to generate two-dimensional grids. To demonstrate the method, a sample grid generated for the ONERA-M6 wing has been presented here. Author

THE PHENOMENON OF VORTEX BREAKDOWN **c02**

Vidyadhar Y. Mudkavi *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 123-135 (For primary document see N94-14598 02-34)

Avail: CASI HC A03/MF A03

Vortex breakdown is an abrupt change of flow structure that occurs in swirling flows. More than 3 decades of research in this area has not shed light upon this very basic fluid dynamical phenomenon. The mechanism that leads to vortex breakdown is very poorly understood despite numerous theoretical and experimental investigations. There is still a need for a coherent theory. In this paper these issues are considered in the form of a review of current literature on the phenomenon of vortex breakdown. Some existing criteria to predict the breakdown are presented. Author

COMPUTATION OF NONEQUILIBRIUM FLOWS USING PNS EQUATIONS

Dinesh K. Prabhu *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 137-151 (For primary document see N94-14598 02-34)

Avail: CASI HC A03/MF A03

The laminar, hypersonic flow of five-species (N2, O2, NO, N, O) nonequilibrium air over a 10 degree axisymmetric cone is computed using a non-iterative, implicit finite-difference scheme. The numerical algorithm is based on central differencing of the inviscid and viscous fluxes. Two gas models are considered in this study - one in which the constituent species are both calorically and thermally perfect and the other in which the constituent species are only thermally perfect. The effects of the two gas models and the types of wall boundary conditions on the computed solution are studied and discussed. Author (revised)

HYPERSONIC VISCOUS FLOW COMPUTATIONS **c02**

S. K. Saxena *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 159-165 (For primary document see N94-14598 02-34)

(NAL Proj. CF-1-121)

Avail: CASI HC A02/MF A03

A brief description of the work currently underway on hypersonic viscous flow computations, based on the solution of thin-layer Navier-Stokes equations employing upwind TVD schemes, is presented. Both van Leer and Roe schemes are considered. Some representative computational results presented indicate that these schemes are quite robust and can provide sharp description of the shocks. The importance of parallel computing on machines like Flosolver and the use of implicit techniques to accelerate the computations is emphasized. The future direction of hypersonic research is indicated. Author

DEVELOPMENT OF A GENERAL PURPOSE MULTIGRID ACCELERATED NAVIER-STOKES SOLVER

J. P. Singh, D. Schwamborn (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Goettingen, Germany.), and C. Kloppmann (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Goettingen, Germany.) *In its* Proceedings of the Fluid Dynamics Symposium in Honour of Professor R. Narasimha on his 60th Birthday Jul. 1993 p 167-179 (For primary document see N94-14598 02-34)

Avail: CASI HC A03/MF A03

The present work describes the development of a fairly general purpose 2-D multigrid accelerated Reynolds-averaged Navier-Stokes solver. For turbulent flows the eddy viscosity is computed using the Baldwin-Lomax model. The code has been successfully used to compute a variety of flows like near-incompressible flows, subsonic flows, flows with massive separation around stall, flow past laminar flow airfoils with long laminar runs, transonic flows with moderate and strong shock, and at supersonic speeds. Results are in good agreement. This shows the robustness and wide applicability of the code. The convergence history in almost all these cases presents a fairly smooth curve with a steep drop to low residue levels. The present level of success in the computation of supersonic flows leads us to expect that this work is directly extendible to hypersonic flows without dissociation effects. Author

REVIEW OF MATHEMATICAL AND PHYSICAL BASIS OF TWO-PHASE FLOW MODELING

M. Bottoni (Argonne National Lab., IL.) and W. Sengpiel Aug. 1992 165 p

(KfK-4759; ETN-93-94189) Copyright Avail: CASI HC A08/MF A02

Starting from a continuum mechanical approach a detailed overview of the deduction of conservation equations for the analytical description of two phase flows by means of an adequate averaging process resulting in a two fluid model and a homogeneous mixture model is given. The mathematical process of averaging leads to macroscopic formulations of stress terms and interfacial interactions terms. These terms depend on microscopic variables and thus give some helpful insight into the physical processes which have to be described by constitutive relations. ESA

The shock-induced combustion of methane-air mixtures in hypersonic flows is investigated using a new reaction mechanism consisting of 19 reacting species and 52 elementary reactions. This reduced model is derived from a full kinetic mechanism via the Detailed Reduction technique. Zero-dimensional computations of several shock-tube experiments are presented first. The reaction mechanism is then combined with a fully implicit Navier-Stokes computational fluid dynamics (CFD) code to conduct numerical simulations of two-dimensional and axisymmetric shock-induced combustion experiments of stoichiometric methane-air mixtures at a Mach number of M = 6.61. Applications to the ram accelerator concept are also presented. Author (revised)

A new computer program is being developed for doing accurate simulations of compressible viscous flows in complex geometries. The code employs the full compressible Navier-Stokes equations. The eddy viscosity model of Baldwin and Lomax is used to model the effects of turbulence on the flow. A cell centered finite volume discretization is used for all terms in the governing equations. The Advection Upwind Splitting Method (AUSM) is used to compute the inviscid fluxes, while central differencing is used for the diffusive fluxes. A four-stage Runge-Kutta time integration scheme is used to march solutions to steady state, while convergence is enhanced by a multigrid scheme, local time-stepping, and implicit residual smoothing. To enable simulations of flows in complex geometries, the code uses composite structured grid systems where all grid lines are continuous at block boundaries (multiblock grids). Example results shown are a flow in a linear cascade, a flow around a circular pin extending between the main walls in a high aspect-ratio channel, and a flow of air in a radial turbine coolant passage. LINEAR INSTABILITY OF CURVED FREE SHEAR LAYERS

William W. Liou Jul. 1993 18 p Presented at the 3rd Shear Flow Control Conference, Orlando, FL, 6-9 Jul. 1993; sponsored by AIAA See also A93-46797

(Contract NCC3-233; RTOP 505-90-5K)

(NASA-TM-106290; ICOMP-93-28; E-8027; NAS 1.15:106290; CMOTT-93-11; AIAA Paper 93-03252) Avail: CASI HC A03/MF A01

The linear inviscid hydrodynamic stability of slightly curved free mixing layers is studied in this paper. The disturbance equation is solved numerically using a shooting technique. Two mean velocity profiles that represent stably and unstably curved free mixing layers are considered. Results are shown for cases of five curvature Richardson numbers. The stability characteristics of the shear layer are found to vary significantly with the introduction of the curvature effects. The results also indicate that, in a manner similar to the Goertler vortices observed in a boundary layer along a concave wall, instability modes of spatially developing streamwise vortex pairs may appear in centrifugally unstable curved mixing layers. A STUDY OF THIN LIQUID SHEET FLOWS

Donald L. Chubb, Frederick D. Calfo, Marc W. McConley (Princeton Univ., NJ.), Matthew S. McMaster (Toledo Univ., OH.), and Abdollah A. Afjeh (Toledo Univ., OH.) Aug. 1993 28 p

(RTOP 506-41-11)

(NASA-TM-106323; E-7854-1; NAS 1.15:106323) Avail: CASI HC A03/MF A01

This study was a theoretical and experimental investigation of thin liquid sheet flows in vacuum. A sheet flow created by a narrow slit of width, W, coalesces to a point at a distance, L, as a result of surface tension forces acting at the sheet edges. As the flow coalesces, the fluid accumulates in the sheet edges. The observed triangular shape of the sheet agrees with the calculated triangular result. Experimental results for L/W as a function of Weber number, We, agree with the calculated result, L/W = the sq. root of 8We. The edge cross sectional shape is found to oscillate from elliptic to 'cigar' like to 'peanut' like and then back to elliptic in the flow direction. A theoretical one-dimensional model was developed that yielded

only elliptic solutions for the edge cross section. At the points where the elliptic shapes occur, there is agreement between theory and experiment.

LOW ALTITUDE PLUME IMPINGEMENT HANDBOOK
Sheldon D. Smith 9 Aug. 1991 56 p Prepared in cooperation with SECA, Inc., Huntsville, AL
(Contract NAS8-38423; NASA Order 1504; NASA Order 1575; NASA Order 1633; NASA Order 1688; NASA Order 1808; SBIR-02.08-8581A)
(NASA-CR-194193; NAS 1.26:194193; SECA-TR-91-8) Avail: CASI HC A04/MF A01

Plume Impingement modeling is required whenever an object immersed in a rocket exhaust plume must survive or remain undamaged within specified limits, due to thermal and pressure environments induced by the plume. At high altitudes inviscid plume models, Monte Carlo techniques along with the Plume Impingement Program can be used to predict reasonably accurate environments since there are usually no strong flowfield/body interactions or atmospheric effects. However, at low altitudes there is plume-atmospheric mixing and potential large flowfield perturbations due to plume-structure interaction. If the impinged surface is large relative to the flowfield and the flowfield is supersonic, the shock near the surface can stand off the surface several exit radii. This results in an effective total pressure that is higher than that which exists in the free plume at the surface. Additionally, in two phase plumes, there can be strong particle-gas interaction in the flowfield immediately ahead of the surface. To date there have been three levels of sophistication that have been used for low altitude plume induced environment predictions. Level 1 calculations rely on empirical characterizations of the flowfield and relatively simple impingement modeling. An example of this technique is described by Piesik. A Level 2 approach consists of characterizing the viscous plume using the SPF/2 code or RAMP2/LAMP and using the Plume Impingement Program to predict the environments. A Level 3 analysis would consist of using a Navier-Stokes code such as the FDNS code to model the flowfield and structure during a single calculation. To date, Level 1 and Level 2 type analyses have been primarily used to perform environment calculations. The recent advances in CFD modeling and computer resources allow Level 2 type analysis to be used for final design studies. Following some background on low altitude impingement, Level 1, 2, and 3 type analysis will be described. Author (revised)

A SMALL-SCALE TURBULENCE MODEL
T. S. Lundgren *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 5-20 (For primary document see N94-14745 02-34)
Avail: CASI HC A03/MF A04; 3 functional color pages

A model for the small-scale structure of turbulence is reformulated in such a way that it may be conveniently computed. The model is an ensemble of randomly oriented structured two dimensional vortices stretched by an axially symmetric strain flow. The energy spectrum of the resulting flow may be expressed as a time integral involving only the enstrophy spectrum of the time evolving two-dimensional cross section flow, which may be obtained numerically. Examples are given in which a k(exp -5/3) spectrum is obtained by this method without using large wave number asymptotic analysis. The k(exp -5/3) inertial range spectrum is shown to be related to the existence of a self-similar enstrophy preserving range in the two-dimensional enstrophy spectrum. The results are insensitive to time dependence of the strain-rate, including even intermittent on-or-off strains. Author (revised)

THE STRUCTURE OF INTENSE VORTICITY IN HOMOGENEOUS ISOTROPIC TURBULENCE
J. Jimenez (Stanford Univ., CA.), A. A. Wray, P. G. Saffman (California Inst. of Tech., Pasadena.), and R. S. Rogallo *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 21-45 (For primary document see N94-14745 02-34)
Avail: CASI HC A03/MF A04; 3 functional color pages

The structure of the intense vorticity regions is studied in numerically simulated homogeneous, isotropic, equilibrium turbulent flow fields at four different Reynolds numbers in the range Re(sub lambda) = 36-171. In accordance with previous investigators, this vorticity is found to be organized in coherent, cylindrical or ribbon-like, vortices ('worms'). A statistical study suggests that they are just especially intense features of the background, O(omega'), vorticity. Their radii scale with the Kolmogorov microscale and their lengths with the integral scale of the flow. An interesting observation is that the Reynolds number based on the circulation of the intense vortices, gamma/nu, increases monotonically with Re(sub lambda), raising the question of the stability of the structures in the limit of Re(sub lambda) approaching infinity. One and two-dimensional statistics of vorticity and strain are presented; they are non-gaussian, and the behavior of their tails depends strongly on the Reynolds number. There is no evidence of convergence to a limiting distribution in our range of Re(sub lambda), even though the energy spectra and the energy dissipation rate show good asymptotic properties in the higher Reynolds number cases. Evidence is presented to show that worms are natural features of the flow and that they do not depend on the particular forcing scheme. Author (revised)

The local nature of the energy cascade in space and time is studied using direct numerical simulation of decaying and forced isotropic turbulence. To examine the concept that large scales evolve into smaller ones, we compute the Lagrangian correlation coefficient between local kinetic energy at different scales. This correlation is found to peak at a Lagrangian time-delay that increases with scale separation. The results show that, on average, the flow of energy to smaller scales is predominantly local in physical space and that the view of eddies decaying into smaller ones while transferring their kinetic energy appears to be, on average, quite realistic. To examine the spectral characteristics of the cascade under unsteady conditions, a pulse of large-scale energy is added to the large-eddy simulation of forced isotropic turbulence. As time progresses, the evolution of this pulse through bands of increasing wavenumbers is studied.

The dependence of subgrid-scale stresses on variables of the resolved field is studied using direct numerical simulations of isotropic turbulence, homogeneous shear flow, and channel flow. The projection pursuit algorithm, a promising new regression tool for high-dimensional data, is used to systematically search through a large collection of resolved variables, such as components of the strain rate, vorticity, velocity gradients at neighboring grid points, etc. For the case of isotropic turbulence, the search algorithm

recovers the linear dependence on the rate of strain (which is necessary to transfer energy to subgrid scales) but is unable to determine any other more complex relationship. For shear flows, however, new systematic relations beyond eddy viscosity are found. For the homogeneous shear flow, the results suggest that products of the mean rotation rate tensor with both the fluctuating strain rate and fluctuating rotation rate tensors are important quantities in parameterizing the subgrid-scale stresses. A model incorporating these terms is proposed. When evaluated with direct numerical simulation data, this model significantly increases the correlation between the modeled and exact stresses, as compared with the Smagorinsky model. In the case of channel flow, the stresses are found to correlate with products of the fluctuating strain and rotation rate tensors. The mean rates of rotation or strain do not appear to be important in this case, and the model determined for homogeneous shear flow does not perform well when tested with channel flow data. Many questions remain about the physical mechanisms underlying these findings, about possible Reynolds number dependence, and, given the low level of correlations, about their impact on modeling. Nevertheless, demonstration of the existence of causal relations between sgs stresses and large-scale characteristics of turbulent shear flows, in addition to those necessary for energy transfer, provides important insight into the relation between scales in turbulent flows.

Nonlocality of the triad interactions in the dissipation range of developed turbulence is investigated by numerical simulation and the quasi-normal theories. It is found that the energy transfer is dominated by nonlocal triad interactions over the wavenumber range 0.1 is less than k/k(sub d) is less than 4, where k(sub d) is the Kolmogorov wave number. The nonlocality of the interaction has a close relation with the power of an algebraic prefactor of the exponential decay of the energy spectrum in the far-dissipation range. Author (revised)

This work is an extension of a project conducted at the previous CTR summer program and was reported by Chen et al. (1990). In that program, the geometry and topology of the dissipating motions in a variety of shear flows was examined. All data was produced by direct numerical simulations (DNS). The partial derivatives of the velocity field were determined at every grid point in the flow and various invariants and related quantities were computed from the velocity gradient tensor. Motions characterized by high rates of kinetic energy dissipation and high enstrophy were of particular interest. Scatter diagrams of the invariants were mapped out and interesting and unexpected patterns were seen. Each type of shear layer produced its own characteristic scatter plot. In the present project, attention is focused on the incompressible plane mixing layer, and the scatter diagrams are replaced with more useful joint probability density contours. Comparison of the topology of the dissipating motions of flows at different Reynolds numbers are made. Also, plane mixing layers at the same Reynolds number but with different initial conditions are compared. Author

ISOTROPY OF SMALL SCALE TURBULENCE

R. A. Antonia (Newcastle Univ., Australia.) and J. Kim *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 123-136 (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

The degree to which local isotropy is satisfied has been examined using direct numerical simulations for a fully developed channel flow. Attention is mainly given to the high wavenumber part of vorticity and temperature derivative spectra. The ratio of these spectra and their isotropic values depends on the particular quantity considered, the departure from isotropy being more pronounced for the temperature derivative than for the vorticity. When the Kolmogorov-normalized wavenumber is sufficiently large, isotropy is satisfied provided the (Kolmogorov-normalized) mean strain rate is sufficiently small. This result appears to be independent of the quantity considered and of the Reynolds number. Author

LES VERSUS DNS: A COMPARATIVE STUDY

L. Shtilman and J. R. Chasnov (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 137-143 (For primary document see N94-14745 02-34)

Avail: CASI HC A02/MF A04; 3 functional color pages

We have performed Direct Numerical Simulations (DNS) and Large Eddy Simulations (LES) of forced isotropic turbulence at moderate Reynolds numbers. The subgrid scale model used in the LES is based on an eddy viscosity which adjusts instantaneously the energy spectrum of the LES to that of the DNS. The statistics of the large scales of the DNS (filtered DNS field or fDNS) are compared to that of the LES. We present results for the transfer spectra, the skewness and flatness factors of the velocity components, the PDF's of the angle between the vorticity and the eigenvectors of the rate of strain, and that between the vorticity and the vorticity stretching tensor. The above LES statistics are found to be in good agreement with those measured in the fDNS field. We further observe that in all the numerical measurements, the trend was for the LES field to be more gaussian than the fDNS field. Future research on this point is planned. Author

BEHAVIOR OF STREAMWISE RIB VORTICES IN A THREE-DIMENSIONAL MIXING LAYER

J. M. Lopez and C. J. Bulbeck *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 147-164 (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

The structure and behavior of a streamwise rib vortex in a direct numerical simulation of a time-developing three-dimensional incompressible plane mixing layer is examined. Where the rib vortex is being stretched, the vorticity vector is primarily directed in the vortex axial direction and the radial and azimuthal velocity distribution is similar to that of a Burger's vortex. In the region where the vortex stretching is negative, there is a change in the local topology of the vortex. The axial flow is decelerated and a negative azimuthal component of vorticity is induced. These features are characteristic of vortex breakdown. The temporal evolution of the rib vortex is similar to the evolution of an axisymmetric vortex in the early stages of vortex breakdown. The effect of vortex breakdown on other parts of the flow is, however, not as significant as the interaction between the rib vortex and other vortices. Author

DIRECT SIMULATION OF POLYMER DRAG REDUCTION IN FREE SHEAR FLOWS AND VORTEX DIPOLES

P. Orlandi, G. M. Homsy (Stanford Univ., CA.), and J. Azaiez (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 165-174 (For primary document see N94-14745 02-34)

Avail: CASI HC A02/MF A04; 3 functional color pages

One of the most efficient techniques for drag reduction is the injection of polymers near a wall which can achieve a reduction in drag up to 80 percent. Several experimental observations tend to indicate that polymers modify the turbulence structures within the buffer layer and show that the changes consist of a weakening of the strength of the streamwise vortices. In this paper, we investigate the effects of viscoelasticity on two different types of flows: the vortex dipole impinging walls to model streamwise vortices in a turbulent boundary layer and the mixing layer that represents free shear flows. For this purpose, we examined three different rheological models: the Oldroyd-B model, the Jeffrey's corotational model, and the FENE-P model. Author

ESTIMATION OF THE VORTEX LENGTH SCALE AND INTENSITY FROM TWO-DIMENSIONAL SAMPLES

D. L. Reuss and W. P. Cheng *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 175-195 Original contains color illustrations (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

A method is proposed for estimating flow features that influence flame wrinkling in reciprocating internal combustion engines, where traditional statistical measures of turbulence are suspect. Candidate methods were tested in a computed channel flow where traditional turbulence measures are valid and performance can be rationally evaluated. Two concepts are tested. First, spatial filtering is applied to the two-dimensional velocity distribution and found to reveal structures corresponding to the vorticity field. Decreasing the spatial-frequency cutoff of the filter locally changes the character and size of the flow structures that are revealed by the filter. Second, vortex length scale and intensity is estimated by computing the ensemble-average velocity distribution conditionally sampled on the vorticity peaks. The resulting conditionally sampled 'average vortex' has a peak velocity less than half the rms velocity and a size approximately equal to the two-point-correlation integral-length scale. Author

RAPID DISTORTION ANALYSIS AND DIRECT SIMULATION OF COMPRESSIBLE HOMOGENEOUS TURBULENCE AT FINITE MACH NUMBER

C. Cambon (Ecole Centrale de Lyon, France.), G. N. Coleman (Stanford Univ., CA.), and N. N. Mansour *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 199-230 (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

The effect of rapid mean compression on compressible turbulence at a range of turbulent Mach numbers is investigated. Rapid distortion theory (RDT) and direct numerical simulation results for the case of axial (one-dimensional) compression are used to illustrate the existence of two distinct rapid compression regimes. These regimes are set by the relationships between the timescales of the mean distortion, the turbulence, and the speed of sound. A general RDT formulation is developed and is proposed as a means of improving turbulence models for compressible flows. Author

INVESTIGATION OF THE DILATATIONAL DISSIPATION IN COMPRESSIBLE HOMOGENEOUS SHEAR FLOW

G. A. Blaisdell and O. Zeman (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 231-245 (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

The dilatational dissipation rate within compressible homogeneous turbulent shear flow is studied using data from direct numerical simulations. It is found that the dilatational dissipation rate is mainly associated with large scale acoustic waves. Eddy shocklets are observed; however, they have little contribution to the average dissipation rate. A mechanism for the generation of eddy shocklets is shown to be the focusing of acoustic waves. Turbulence models for the dilatational dissipation rate are compared with data from the simulations. It is found that the formulation of Zeman used by Viegas & Rubesin to calculate a compressible mixing layer agrees well with the numerical simulation results for turbulent Mach numbers less than 0.3. However, it is also found that, for the Mach number range occurring in mixing layers, the model does not accurately represent the theory upon which it is based. Author (revised)

VORTEX-INDUCED DISTURBANCE FIELD IN A COMPRESSIBLE SHEAR LAYER

D. Papamoschou and S. K. Lele (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 259-276 (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

The disturbance field induced by a small isolated vortex in a compressible shear layer is studied using direct simulation in a convected frame. The convective Mach number, M(sub c), is varied from 0.1 to 1.25. The vorticity perturbation is rapidly sheared by the mean velocity gradient. The resulting disturbance pressure field is observed to decrease both in magnitude and extent with increasing M(sub c), becoming a narrow transverse zone for M(sub c) greater than 0.8. A similar trend is seen for the perturbation velocity magnitude and for the Reynolds shear stress. By varying the vortex size, we verified that the decrease in perturbation levels is due to the mean-flow Mach number and not the Mach number across the vortex. At high M(sub c), the vortex still communicates with the edges of the shear layer, although communication in the mean-flow direction is strongly inhibited. The growth rate of perturbation kinetic energy declines with M(sub c) primarily due to the reduction in shear stress. For M(sub c) greater than or equal to 0.6, the pressure dilatation also contributes to the decrease of growth rates. Calculation of the perturbation field induced by a vortex doublet revealed the same trends as in the single-vortex case, illustrating the insensitivity of the Mach-number effect to the specific form of initial conditions. EVOLUTION OF THE SHOCK FRONT AND TURBULENCE STRUCTURES IN THE SHOCK/TURBULENCE INTERACTION

N. Kevlahan, K. Mahesh (Stanford Univ., CA.), and S. Lee (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 277-292 (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

The interaction of a weak shock front with isotropic turbulence has been investigated using Direct Numerical Simulation (DNS). Two problems were considered: the ability of the field equation (the equation for a propagating surface) to model the shock; and a quantitative study of the evolution of turbulence structure using the database generated by Lee et al. Field equation model predictions for front shape have been compared with DNS results; good agreement is found for shock wave interaction with 2D turbulence and for a single steady vorticity wave. In the interaction of 3D isotropic turbulence with a normal shock, strong alignment of vorticity with the intermediate eigenvector of the rate of strain tensor (S(sup *)(sub

ij) = S(sub ij) - (1/3)(delta(sub ij))(S(sub kk))) is seen to develop upstream of the shock and to be further amplified on passage through the shock. Vorticity tends to align at 90 deg to the largest eigenvector, but there is no preferred alignment with the smallest eigenvector. Upstream of the shock, the alignments continue to develop even after the velocity derivative skewness saturates. There is a significant tendency, which increases with time throughout the computational domain, for velocity to align with vorticity. The alignment between velocity and vorticity is strongest in eddy regions and weakest in convergence regions. Author (revised)

A TRANSPORT EQUATION FOR EDDY VISCOSITY

P. A. Durbin (Stanford Univ., CA.) and Z. Yang *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 293-303 (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

A transport equation for eddy viscosity is proposed for wall bounded turbulent flows. The proposed model reduces to a quasi-homogeneous form far from surfaces. Near to a surface, the nonhomogeneous effect of the wall is modeled by an elliptic relaxation model. All the model terms are expressed in local variables and are coordinate independent; the model is intended to be used in complex flows. Turbulent channel flow and turbulent boundary layer flows with/without pressure gradient are calculated using the present model. Comparisons between model calculations and direct numerical simulation or experimental data show good agreement. Author

DNS AND MODELING OF THE INTERACTION BETWEEN TURBULENT PREMIXED FLAMES AND WALLS

T. J. Poinsot and D. C. Haworth (General Motors Corp., Warren, MI.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 307-323 (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

The interaction between turbulent premixed flames and walls is studied using a two-dimensional full Navier-Stokes solver with simple chemistry. The effects of wall distance on the local and global flame structure are investigated. Quenching distances and maximum wall heat fluxes during quenching are computed in laminar cases and are found to be comparable to experimental and analytical results. For turbulent cases, it is shown that quenching distances and maximum heat fluxes remain of the same order as for laminar flames. Based on simulation results, a 'law-of-the-wall' model is derived to describe the interaction between a turbulent premixed flame and a wall. This model is constructed to provide reasonable behavior of flame surface density near a wall under the assumption that flame-wall interaction takes place at scales smaller than the computational mesh. It can be implemented in conjunction with any of several recent flamelet models based on a modeled surface density equation, with no additional constraints on mesh size or time step. Author

THE EVOLUTION EQUATION FOR THE FLAME SURFACE DENSITY IN TURBULENT PREMIXED COMBUSTION **c25**

A. Trouve and T. Poinsot (Institut de Mecanique des Fluides de Toulouse, France.) *In its* Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 325-343 (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

One central ingredient in flamelet models for turbulent premixed combustion is the flame surface density. This quantity conveys most of the effects of the turbulence on the rate of energy release and is obtained via a modeled transport equation, called the Sigma-equation. Past theoretical work has produced a rigorous approach that leads to an exact, but unclosed, formulation for the turbulent Sigma-equation. In this exact Sigma-equation, it appears that the dynamical properties of the flame surface density are determined by a single parameter, namely the turbulent flame stretch. Unfortunately, the flame surface density and the turbulent flame stretch are not available from experiments and, in the absence of experimental data, little is known on the validity of the closure assumptions used in current flamelet models. Direct Numerical Simulation (DNS) is the obvious, complementary approach to get basic information on these fundamental quantities. Three-dimensional DNS of premixed flames in isotropic turbulent flow is used to estimate the different terms appearing in the Sigma-equation. A new methodology is proposed to provide the source and sink terms for the flame surface density, resolved both temporally and spatially throughout the turbulent flame brush. Using this methodology, the effects of the Lewis number on the rate of production of flame surface area are described in great detail and meaningful comparisons with flamelet models can be performed. The analysis reveals in particular the tendency of the models to overpredict flame surface dissipation as well as their inability to reproduce variations due to thermo-diffusive phenomena. Thanks to the detailed information produced by a DNS-based analysis, this type of comparison not only underscores the shortcomings of current models but also suggests ways to improve them. NUMERICAL SIMULATIONS OF TURBULENT PREMIXED H2/O2/N2 FLAMES WITH COMPLEX CHEMISTRY **c25**

M. Baum, T. J. Poinsot (Institut de Mecanique des Fluides de Toulouse, France.), and D. C. Haworth (General Motors Corp., Warren, MI.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 345-366 Original contains color illustrations (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

Premixed stoichiometric H2/O2/N2 flames propagating in two-dimensional turbulence were studied using direct numerical simulation (simulations in which all fluid and thermochemical scales are fully resolved) including realistic chemical kinetics and molecular transport. Results are compared with earlier zero-chemistry (flame sheet) and one-step chemistry simulations. Consistent with the simpler models, the turbulent flame with realistic chemistry aligns preferentially with extensive strain rates in the tangent plane and flame curvature probability density functions are close to symmetric with near-zero means. By contrast to simple-chemistry results with non-unity Lewis numbers (ratio of thermal to species diffusivity), local flame structure does not correlate with curvature but rather with tangential strain rate. Turbulent straining results in substantial thinning of the flame relative to the steady unstrained laminar case. Heat release and H2O2 contours remain thin and connected ('flamelet-like') while species including H-atom and OH are more diffuse. Peak OH concentration occurs well behind the peak heat-release zone. The feasibility of incorporating realistic chemistry into full turbulence simulations to address issues such as pollutant formation in hydrocarbon-air flames is suggested. Author (revised)

EFFECT OF FINITE-RATE CHEMISTRY AND UNEQUAL SCHMIDT NUMBERS ON TURBULENT NON-PREMIXED FLAMES MODELED WITH SINGLE-STEP CHEMISTRY **c25**

J. H. Chen, S. Mahalingam (Colorado Univ., Boulder.), I. K. Puri (Illinois Univ., Chicago.), and L. Vervisch (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 367-387 Sponsored in part by DOE (For primary document see N94-14745 02-34)

Avail: CASI HC A03/MF A04; 3 functional color pages

The interaction between a quasi-laminar flame and a turbulent flowfield is investigated through direct numerical simulations (DNS) of reacting flow in two- and three-dimensional domains. Effects due to finite-rate chemistry are studied using a single step global reaction A (fuel) + B (oxidizer) yields P (product), and by varying a global Damkoehler number, as a result of which the turbulence-chemistry interaction in the flame is found to generate a wide variety of conditions, ranging from near-equilibrium to near-extinction. Differential diffusion effects are studied by changing the Schmidt number of one reactive species to one-half. It is observed that laminar flamelet response is followed within the turbulent flowfield, except in regions where transient effects seem to dominate. Author (revised)

STRUCTURE OF TURBULENT NON-PREMIXED FLAMES MODELED WITH TWO-STEP CHEMISTRY **c25**

J. H. Chen, S. Mahalingam (Colorado Univ., Boulder.), I. K. Puri (Illinois Univ., Chicago.), and L. Vervisch (Stanford Univ., CA.) *In* Stanford Univ., Studying Turbulence Using Numerical Simulation Databases. 4: Proceedings of the 1992 Summer Program Nov. 1992 p 389-402 Sponsored in part by DOE (For primary document see N94-14745 02-34)
Avail: CASI HC A03/MF A04; 3 functional color pages

Direct numerical simulations of turbulent diffusion flames modeled with finite-rate, two-step chemistry, A + B yields I, A + I yields P, were carried out. A detailed analysis of the turbulent flame structure reveals the complex nature of the penetration of various reactive species across two reaction zones in mixture fraction space. Due to this two zone structure, these flames were found to be robust, resisting extinction over the parameter ranges investigated. As in single-step computations, mixture fraction dissipation rate and the mixture fraction were found to be statistically correlated. Simulations involving unequal molecular diffusivities suggest that the small scale mixing process and, hence, the turbulent flame structure is sensitive to the Schmidt number. Author (revised)

Direct numerical simulations of a single-step irreversible chemical reaction with non-premixed reactants in forced isotropic turbulence at R(sub lambda) = 63, Da = 4.0, and Sc = 0.7 were made using 128 Fourier modes to obtain joint probability density functions (pdfs) and other statistical information to parameterize and test a Fokker-Planck turbulent mixing model. Preliminary results indicate that the modeled gradient stretching term for an inert scalar is independent of the initial conditions of the scalar field. The conditional pdf of scalar gradient magnitudes is found to be a function of the scalar until the reaction is largely completed. Alignment of concentration gradients with local strain rate and other features of the flow were also investigated. Author (revised)

(ETN-93-94395) Avail: CASI HC A08/MF A02

A method for solving Navier-Stokes continuity and energy equations with reduced computation time and memory allocation is presented. A three dimensional stream function formulation with four partial differential equations was given and reduced to a two dimensional form. Two particular cases were considered such as Benard problem and low Prandtl fluids. The Newton chord process was used for numerical solution of the two dimensional formulation. A partial linear differential equation system as a block three diagonal system and an eigenvalue problem in a Banach space were obtained. A local and global continuity method was used for discretization. Results obtained for free and Marangoni convection are presented, which show the importance of boundary condition choice.

A viscous or inviscid cylindrical jet with surface tension in a vacuum tends to pinch due to the mechanism of capillary instability. Similarity solutions are constructed which describe this phenomenon as a critical time is encountered, for two physically distinct cases: inviscid jets governed by the Euler equations and highly viscous jets governed by the Stokes equations. In both cases the only assumption imposed is that at the time of pinching the jet shape has a radial length scale which is smaller than the axial length scale. For the inviscid case, we show that our solution corresponds exactly to one member of the one-parameter family of solutions obtained from slender jet theories and the shape of the jet is locally concave at breakup. For highly viscous jets our theory predicts local shapes which are monotonic increasing or decreasing indicating the formation of a mother drop connected to the jet by a thin fluid tube. This qualitative behavior is in complete agreement with both direct numerical simulations and experimental observations. Author (revised)

TOWARD A QUASI-LINEAR CLOSURE FOR COMPRESSIBLE TURBULENCE
J. A. H. Futterman and W. P. Dannevik Mar. 1993 23 p Presented at the 4th International Workshop on the Physics of Compressible Turbulent Mixing, Cambridge, England, 29 Mar. - 1 Apr. 1993
(Contract W-7405-eng-48)
(DE93-017185; UCRL-JC-112562; CONF-9303126-6) Avail: CASI HC A03/MF A01

The authors are developing a quasilinear closure model for compressible turbulence based on a transformation of the averaged Navier-Stokes equations into a form that is at most quadratically nonlinear in the mean and fluctuating variables. Following the transformation, they discard third-order cumulants, in hope of arriving at a one-point closure model without adjustable parameters which will be applicable to systems undergoing rapid deformation, such as imploding Inertial Confinement Fusion capsules. SIMULATION OF PREBURNER SPRAYS, VOLUME 1 Final Report
May 1993 5 p Prepared in cooperation with Imperial Coll. of Science and Technology, London, England
(Contract NAS8-38872)
(NASA-CR-193844; NAS 1.26:193844; SRA-R93-9083-F-Vol-1) Avail: CASI HC A01/MF A01

Under the present contract a study was made on the characteristics of the sprays of coaxial injectors with particular emphasis on those aspects relevant to the performance of rocket engines. The technical effort was performed primarily by Imperial College of Science and Technology and the details of this effort are contained in the accompanying technical report by Hardalupas and Whitelaw, which forms Vol. 2 of the report. The role of Scientific Research Associates was review of material, initial direction of the technical effort and review of all reports. The study considered characteristics of sprays under a variety of conditions. Control of these sprays is important as the spray details can control both rocket combustion stability and efficiency. Imperial College considered the following: first, measurement of the size and rate of spread of the sprays produced by single coaxial airblast nozzles with axial gaseous stream. The local size, velocity and flux characteristics for a wide range of gas and liquid flowrates were measured and the results were correlated with the conditions of the spray at the nozzle exit. Second, examination of the effect of the geometry of single coaxial airblast atomizers on spray characteristics. The gas and liquid tube diameters were varied over a range of values, the liquid tube recess was varied and the shape of the exit of the gaseous jet was varied from straight to converging. Third, quantification of the effect of swirl in the gaseous stream on the spray characteristics produced by single coaxial airblast nozzles. Fourth, quantification of the effect of reatomization by impingement of the spray on a flat disc positioned around 200 mm from the nozzle exit. This models spray impingement on the turbopump dome during the startup process of the preburner of the Space Shuttle Main Engine (SSME). Fifth, study of the interaction between multiple sprays without and with swirl in their gaseous stream. The spray characteristics of single nozzles were compared with that of three identical nozzles with their axis at a small distance from each other. This study simulates the sprays in the preburner of the SSME, where there are around 260 elements on the faceplate of the combustion chamber. And lastly, design an

experimental facility to study the characteristics of sprays at high pressure conditions and at supercritical pressure and temperature for the gas but supercritical pressure and subcritical temperature for the liquid.

This review discusses the status of strain sensing technology for high temperature applications. Technologies covered are those supported by NASA such as required for applications in hypersonic vehicles and engines, advanced subsonic engines, as well as material and structure development. The applications may be at temperatures of 540 C (1000 F) to temperatures in excess of 1400 C (2500 F). The most promising technologies at present are the resistance strain gage and remote sensing schemes. Resistance strain gages discussed include the BCL gage, the LaRC compensated gage, and the PdCr gage. Remote sensing schemes such as laser based speckle strain measurement, phase-shifting interferometry, and x-ray extensometry are discussed. Present status and limitations of these technologies are presented. Author (revised)

A SURVEY AND ANALYSIS OF EXPERIMENTAL HYDROGEN SENSORS
Gary W. Hunter Oct. 1992 16 p
(RTOP 590-21-11)
(NASA-TM-106300; E-8040; NAS 1.15:106300) Avail: CASI HC A03/MF A01

In order to ascertain the applicability of hydrogen sensors to aerospace applications, a survey was conducted of promising experimental point-contact hydrogen sensors and their operation was analyzed. The techniques discussed are metal-oxide-semiconductor or MOS based sensors, catalytic resistor sensors, acoustic wave detectors, and pyroelectric detectors. All of these sensors depend on the interaction of hydrogen with Pd or a Pd-alloy. It is concluded that no single technique will meet the needs of aerospace applications but a combination of approaches is necessary. The most promising combination is an MOS based sensor with a catalytic resistor.

DEVELOPMENT OF A PORTABLE MULTISPECTRAL THERMAL INFRARED CAMERA Final Report
Frederick G. Osterwisch 30 May 1991 24 p
(Contract NAS7-1063; SBIR-08.06-5649)
(NASA-CR-191340; NAS 1.26:191340) Avail: CASI HC A03/MF A01

The purpose of this research and development effort was to design and build a prototype instrument designated the 'Thermal Infrared Multispectral Camera' (TIRC). The Phase 2 effort was a continuation of the Phase 1 feasibility study and preliminary design for such an instrument. The completed instrument designated AA465 has application in the field of geologic remote sensing and exploration. The AA465 Thermal Infrared Camera (TIRC) System is a field-portable multispectral thermal infrared camera operating over the 8.0 - 13.0 micron wavelength range. Its primary function is to acquire two-dimensional thermal infrared images of user-selected scenes. Thermal infrared energy emitted by the scene is collected, dispersed into ten 0.5 micron wide channels, and then measured and recorded by the AA465 System. This multispectral information is presented in real time on a color display to be used by the operator to identify spectral and spatial variations in the scenes emissivity and/or irradiance. This fundamental instrument capability has a wide variety of commercial and research applications. While ideally suited for two-man operation in the field, the AA465 System can be transported and operated effectively by a single user. Functionally, the instrument operates as if it were a single exposure camera. System measurement sensitivity requirements dictate relatively long (several minutes) instrument exposure times. As such, the instrument is not suited for recording time-variant information. The AA465 was fabricated, assembled, tested, and documented during this Phase 2 work period. The detailed design and fabrication of the instrument was performed during the period of June 1989 to July 1990. The software development effort and instrument integration/test extended from July 1990 to February 1991. Software development included an operator interface/menu structure, instrument internal control functions, DSP image processing code, and a display algorithm coding program. The instrument was delivered to NASA in March 1991. Potential commercial and research uses for this instrument are in its primary application as a field geologists exploration tool. Other applications have been suggested but not investigated in depth. These are measurements of process control in commercial materials processing and quality control functions which require information on surface heterogeneity. Derived from text

CALCULATION OF THE REQUIRED SENSOR ACCURACY TO OBTAIN A SPECIFIED STATE ESTIMATION ACCURACY [SHITEISARETA JOUTAI SUITEI SEIDO JITSUGEN NO TAMENO SENSA YOUKYUU SEIDO NO DOUSHUTSU]

Shuuichi Sasa and Masahiko Nagayasu Jul. 1992 8 p In JAPANESE
(NAL-TR-1173; JTN-93-80490) Avail: CASI HC A02/MF A01

For the design of sensor systems for flight test data acquisition, the determination of necessary accuracy of the sensors is important. In this report, one method is presented to calculate the sensor accuracy to obtain a specified state estimation accuracy by a Kalman filter. This is an inverse problem of a state estimation problem in which observation sensor or input sensor accuracy is obtained by an optimization method. The Gauss-Newton method is applied in the iterative optimization calculation, and the basic performance is presented by numerical example using 3rd order linear system model. Author (NASDA)

ATTITUDE DETERMINATION OF STRATOSPHERIC BALLOONS USING KALMAN FILTERS M.S. Thesis [DETERMINACAO DE ATITUDE DE BALOES ESTRATOSFERICOS UTILIZANDO FILTROS DE KALMAN]

Luiz deSiqueiraMartinsFilho Dec. 1992 120 p In PORTUGESE
(INPE-5498-TDI/513) Avail: CASI HC A06/MF A02

The application of state estimation, via extended Kalman filter, in attitude determination of a balloon borne telescope was studied. This astrophysical experiment - the MASCO project requires a pointing accuracy with maximum error of 20 arcmin in the stabilization phase. The attitude determination uses three gyroscope axis, a two axis sun sensor and a three axis magnetometer. The cinematic model of the gyroscope substitutes the telescope motion dynamic model in the Kalman filter and the attitude description is performed using quaternions. A second configuration of estimation uses constant Kalman gain for calculus simplification and processing time reduction. The two configurations are analyzed and compared through digital computer simulations. Author (revised)

ISOLATION OF A PIEZORESISTIVE ACCELEROMETER USED IN HIGH ACCELERATION TESTS

V. I. Bateman, F. A. Brown, and N. T. Davie 1992 20 p Presented at the 17th Transducer Workshop, San Diego, CA, 22-24 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-013764; SAND-92-2712C; CONF-9306170-1) Avail: CASI HC A03/MF A01

Both uniaxial and triaxial shock isolation techniques for a piezoresistive accelerometer have been developed for pyroshock and impact tests. The uniaxial shock isolation technique has demonstrated acceptable characteristics for a temperature range of -50 to +186 F and a frequency bandwidth of DC to 10 kHz. The triaxial shock isolation technique has demonstrated acceptable results for a temperature range of -50 to 70 F and a frequency bandwidth of DC to 10 kHz. These temperature ranges, that are beyond the accelerometer manufacturer's operational limits of -30 and +150 F, required the calibration of accelerometers at high shock levels and at the temperature extremes of -50 and +160 F. The purposes of these calibrations were to insure that the accelerometers operated at the field test temperatures and to provide an accelerometer sensitivity at each test temperature. Since there is no NIST-traceable (National Institute of Standards and Technology traceable) calibration capability at shock levels of 5,000 - 15,000 g for the temperature extremes of -50 and +160 F, a method for calibrating and certifying the Hopkinson bar with a transfer standard was developed. Time domain and frequency domain results are given that characterize the Hopkinson bar. The NIST-traceable accuracy for the standard accelerometer in shock is +-5%. The Hopkinson bar has been certified by the Sandia Secondary Standards Division with an uncertainty of 6%. DOE

Varian is carrying out the development of high-power, cw gyrotrons at frequencies ranging from 85-140 GHz. An experimental tube employing a TE(sub 22,2,1)-mode cavity and utilizing an output coupling concept where the collection of the spent electron beam is separated from the outgoing microwave power has been designed and constructed. In initial tests on the tube, output powers of 450-500 kW have been obtained for pulse durations out to 2.5 seconds, in the desired TE(sub 22,2,1) mode at a frequency of 110 GHz. Electron cyclotron resonance heating (ECRH) requirements for planned magnetic fusion experiments such as the International Thermonuclear Experimental Reactor (ITER) will require millimeter-wave sources capable of output powers of at least 1 MW cw at frequencies in the range, 100-200 GHz. Initial megawatt-level development work at Varian resulted in a gyrotron design that was tested to output powers of 1 MW for short pulses (approximately 1 ms) and 400 kW for 0.5-s pulses at a frequency of 140 GHz. Output powers up to 1 MW have been achieved for short pulses (1 ms). Future tests on this and subsequent experimental tubes will be aimed at achieving 1 MW power levels under long-pulse and ultimately, cw conditions. DOE

KALMAN FILTER INPUT ESTIMATION [KARUMAN FIRUTA NIYORU NYUURYOKU SUITEI]

Shuuichi Sasa and Masahiko Nagayasu Nov. 1992 7 p In JAPANESE
(NAL-TR-1182; JTN-93-80504) Avail: CASI HC A02/MF A01

As system output includes information concerning system input, it seems possible that system output can be used to estimate noisy system input. For Single Input Single Output (SISO) systems, the problem of input estimation using a Kalman filter is examined. Since the problem is different from an ordinary Kalman filter problem, it is first modified to an ordinary Kalman filter problem, and the input estimation accuracy is then calculated from the measurement accuracy through the Riccati equation. The input accuracy for an integrator system is analyzed, and a sinusoidal input is estimated using the simulated output of an integrator system.

ROVER IMAGING SYSTEM FOR THE MARS ROVER/SAMPLE RETURN MISSION Final Report

28 Feb. 1993 4 p Sponsored by Langley Research Center
(NASA-CR-193413; NAS 1.26:193413) Avail: CASI HC A01/MF A01

In the past year, the conceptual design of a panoramic imager for the Mars Environmental Survey (MESUR) Pathfinder was finished. A prototype camera was built and its performace in the laboratory was tested. The performance of this camera was excellent. Based on this work, we have recently proposed a small, lightweight, rugged, and highly capable Mars Surface Imager (MSI) instrument for the MESUR Pathfinder mission. A key aspect of our approach to optimization of the MSI design is that we treat image gathering, coding, and restoration as a whole, rather than as separate and independent tasks. Our approach leads to higher image quality, especially in the representation of fine detail with good contrast and clarity, without increasing either the complexity of the camera or the amount of data transmission. We have made significant progress over the past year in both the overall MSI system design and in the detailed design of the MSI optics. We have taken a simple panoramic camera and have upgraded it substantially to become a prototype of the MSI flight instrument. The most recent version of the camera utilizes miniature wide-angle optics that image directly onto a 3-color, 2096-element CCD line array. There are several data-taking modes, providing resolution as high as 0.3 mrad/pixel. Analysis tasks that were performed or that are underway with the test data from the prototype camera include the following: construction of 3-D models of imaged scenes from stereo data, first for controlled scenes and later for field scenes; and checks on geometric fidelity, including alignment errors, mast vibration, and oscillation in the drive system. We have outlined a number of tasks planned for Fiscal Year '93 in order to prepare us for submission of a flight instrument proposal for MESUR Pathfinder.

PHOTOGRAMMETRIC METHODS FOR TRAJECTORY MEASUREMENTS

A. J. L. Willekens 15 Apr. 1991 33 p Presented at the SFTE 4th European Mini Symposium, Rome, Italy, 1991

(NLR-TP-91166-U; ETN-93-94336) Avail: CASI HC A03/MF A01

A photogrammetric method for trajectory measurements in flight testing at short range is discussed. A theoretical overview of the method used is given, this being a combination of a camera and equipment on board of the aircraft like Global Positioning System (GPS) or inertial navigation system and a baro-altimeter. On the ground a minimum of equipment is required: only surveyed ground control points are needed. The accuracy further depends strongly on the method used, so different methods are discussed. Operational aspects also are important for the selected method. The resulting method is relatively simple, quite accurate, and can be used under many different conditions. The practical aspects are discussed in chronological order. This illustrates how the method evolved from a simple camera and equally simple calculations to the equipment nowadays. The manual work involved decreased with each amelioration. Some operational aspects of the new system are discussed. Based on today's system, some remarks of future evolutions can be made. Here is the question whether and where can the Charge Coupled Device (CCD) (video) camera replace the film used today. This question has more than only technical relevance: operational issues are equally important. ESA

SUPPRESSION OF BRIGHT OBJECTS USING A SPATIAL LIGHT MODULATOR WHEN IMAGING WITH CCD- AND IMAGE INTENSIFIED CAMERAS [UNDERTRYCKING AV OBJEKTER MED HOEY LUMINANS VED HJELP AV EN ROMLIG LYSMODULATION UNDER AVBILDNING MED CCD- OG LYSFORSTERKNINGSKAMERA]

Torbjoern Groeder 28 Jan. 1993 143 p In NORWEGIAN Original contains color illustrations

(FFI-93/7008; ETN-93-94455) Avail: CASI HC A07/MF A02

The operation of CCD (Charge Coupled Devices) and intensified cameras is described with emphasis on the problems caused by local overexposure of the image sensor. In trying to reduce the amount of blooming in the image, a transmissive graphic Liquid Crystal Display (LCD) operating as a spatial light modulator was placed in front of the cameras, and the transmission of the display elements was dynamically controlled in real time from a Personal Computer (PC). By activating the LCD elements in front of strongly illuminated areas of the image sensor, improvement of the image quality was demonstrated. Various types of LCDs were studied in trying to learn which ones would be best suited for this particular application, and this work may suggest a new application area for LCD's. ESA

IMAGES CONSTRUCTED FROM COMPUTED FLOW FIELDS

Leslie A. Yates [1992] 17 p

(Contract NCC2-583)

(NASA-CR-194397; NAS 1.26:194397) Avail: CASI HC A03/MF A01

A method for constructing interferograms, schlieren, and shadowgraphs from ideal- and real-gas, two- and three-dimensional computed flow fields is described. The computational grids can be structured or unstructured, and multiple grids are an option. The constructed images are compared to experimental images for several types of flow, including a ramp, a blunt-body, a nozzle, and a reacting flow. The constructed images simulate the features observed in the experimental images. They are sensitive to errors in the flow-field solutions and can be used to identify solution errors. In addition, techniques for obtaining phase shifts from experimental finite-fringe interferograms and for removing experimentally induced phase-shift errors are discussed. Both the constructed images and calculated phase shifts can be used for validation of computational fluid dynamics (CFD) codes. Author

DEVELOPMENT OF AN AUTOMATED FILM-READING SYSTEM FOR BALLISTIC RANGES

Leslie A. Yates [1992] 13 p

(Contract NCC2-583)

(NASA-CR-194398; NAS 1.26:194398) Avail: CASI HC A03/MF A01

Software for an automated film-reading system that uses personal computers and digitized shadowgraphs is described. The software identifies pixels associated with fiducial-line and model images, and least-squares procedures are used to calculate the positions and orientations of the images. Automated position and orientation readings for sphere and cone models are compared to those obtained using a manual film reader. When facility calibration errors are removed from these readings, the accuracy of the automated readings is better than the pixel resolution, and it is equal to, or better than, the manual readings. The effects of film-reading and facility-calibration errors on calculated aerodynamic coefficients is discussed. Author

TOMOGRAPHIC METHODS IN FLOW DIAGNOSTICS

Arthur J. Decker Sep. 1993 19 p Presented at the Summer School on Optical Diagnostics for Flow Processes, Roskilde, Denmark, 26 Sep. - 2 Oct. 1993; cosponsored by Danish Research Academy and The European Community Programme on Human Capital and Mobility

(RTOP 505-62-50)

(NASA-TM-106330; E-8091; NAS 1.15:106330) Avail: CASI HC A03/MF A01

This report presents a viewpoint of tomography that should be well adapted to currently available optical measurement technology as well as the needs of computational and experimental fluid dynamists. The goals in mind are to record data with the fastest optical array sensors; process the data with the fastest parallel processing technology available for small computers; and generate results for both experimental and theoretical data. An in-depth example treats interferometric data as it might be recorded in an aeronautics test facility, but the results are applicable whenever fluid properties are to be measured or applied from projections of those properties. The paper discusses both computed and neural net calibration tomography. The report also contains an overview of key definitions and computational methods, key references, computational problems such as ill-posedness, artifacts, missing data, and some possible and current research topics. HIGH FRAME RATE THERMAL IMAGER FOR HYPERSONIC WIND TUNNEL APPLICATIONS Ph.D. Thesis - Paris-Sud Univ. [CAMERA INFRAROUGE A FREQUENCE IMAGE ELEVEE POUR APPLICATIONS EN SOUFFLERIE HYPERSONIQUE]

Stephane Barbe Nov. 1992 185 p In FRENCH Original contains color illustrations

(ONERA-NT-1992-12; ETN-93-93971) Avail: CASI HC A09/MF A02

Infrared thermography is used to derive heat transfer coefficients from thermal mappings of wind tunnel models. Due to the short duration of the runs in hypersonic F4 facilities, a high frame rate infrared camera is needed to record the thermal variations of the model. In accordance with F4 wind tunnel specifications, a 400 Hz frame rate thermal imager was developed. An HgCdTe 64 by 64 focal plane array in the 3 to 5 micrometers spectral band is used. The complete set of hardware devices and software is described. The F4 wind tunnel infrared background variation is estimated, in order to evaluate photometric measurement errors. After photometric and spatial criteria analysis, an experimental setup is used to measure camera sensitivity and to test the fixed pattern correction for different sets of parameter values. The minimum resolved temperature difference is less than 0.1K for 50K temperature range with 300K background. To check that the instrument works properly at the 400 Hz frame rate, a frame sequence of a fast thermal event is shown. The camera was then tested in the F4 wind tunnel. ESA

A CALIBRATION PROCEDURE FOR RADIATION BUDGET RADIOMETERS AND ITS INFLUENCE ON INTERPRETATION OF MEASURED VALUES [EIN EICHVERFAHREN FUER STRAHLUNGSBILANZRADIOMETER UND SEIN EINFLUSS AUF DIE INTERPRETATION DER MESSWERTE]

Johannes Mueller 1991 129 p In GERMAN

(Contract BMFT-01-QS-88168)

(Mitt-82; ETN-93-94382) Avail: CASI HC A07/MF A02

A procedure for the calibration of the spectral broadband satelliteborne radiometer 'ScaRaB' (Scanner for Radiation Budget) is developed. The calibration was divided into a preflight ground calibration and an onboard calibration. The onboard calibration was repeated five times per orbit. During the presentation of the calibration process, the influence of the properties of calibration sources on the results of the measurements was analyzed. A procedure was developed to minimize the necessary corrections on the measurements by the choice of sources. The calibration sources were investigated, and the achievable accuracies were evaluated. The spectral qualities of the ground calibration sources determine the conversion of the filtered radiances into unfiltered radiances. A black body source and a calibrated solar diffusor were supposed to be sufficient for the ground calibration. A black body simulator, a calibration lamp, and a solar diffusor were the designated onboard sources. They are revised critically with respect to homogeneity, isotropy, and spectral emission. The black body simulators fulfill these requirements well. The isotropy of the lamp sources was tolerable, but should be improved in future. The onboard solar diffusors are not sufficient in their present design. An alternative concept of solar diffusors is presented. ESA

IMAGING FOURIER TRANSFORM SPECTROMETER

C. L. Bennett, M. R. Carter, D. J. Fields, and J. Hernandez 14 Apr. 1993 11 p Presented at the Society of Photo-Optical Instrumentation Engineers OE/Aerospace Science and Sensing Meeting, Orlando, FL, 11-16 Apr. 1993

(Contract W-7405-eng-48)

(DE93-017193; UCRL-JC-113273; CONF-930445-18) Avail: CASI HC A03/MF A01

The operating principles of an Imaging Fourier Transform Spectrometer (IFTS) are discussed. The advantages and disadvantages of such instruments with respect to alternative imaging spectrometers are discussed. The primary advantages of the IFTS are the capacity to acquire more than an order of magnitude more spectral channels than alternative systems with more than an order of magnitude greater etendue than for alternative systems. The primary disadvantage of IFTS, or FTS in general, is the sensitivity to temporal fluctuations, either random or periodic. Data from the IRIFTS prototype instrument, sensitive in the infrared (IR), are presented having a spectral sensitivity of 0.01 absorbance units, a spectral resolution of 6 cm(exp -1) over the range 0 to 7899 cm(exp -1), and a spatial resolution of 2.5 mr. DOE

TWO COLOR HOLOGRAPHIC INTERFEROMETRY FOR MICROGRAVITY APPLICATION Technical Report No. 5, 1 Apr. - 1 Oct. 1993

James D. Trolinger Oct. 1993 19 p

(Contract NAS8-39402)

(NASA-CR-194424; NAS 1.26:194424; DCN-1-2-ES-44818) Avail: CASI HC A03/MF A01

Holographic interferometry is a primary candidate for the measurement of temperature and concentration in various crystal growth experiments destined for space. The method measures refractive index changes in the experiment test cell. A refractive index change can be caused by concentration changes, temperature changes, or a combination of temperature and concentration changes. If the refractive index changes are caused by temperature and concentration changes occurring simultaneously in the experiment test cell, the contributions by the two effects cannot be separated by conventional measurement methods. By using two wavelengths, two independent interferograms can be produced from the reconstruction of the hologram. The two interferograms will be different due to dispersion properties of fluid materials. These differences provide the additional information that allows the separation of simultaneously occurring temperature and concentration gradients. There is no other technique available that can provide this type of information. The primary objectives of this effort are to experimentally verify the mathematical theory of two color holographic interferometry and to determine the practical value of this technique for space application. To achieve these objectives, the accuracy and sensitivity of the technique must be determined for geometry's and materials that are relevant to the Materials Processing in the Space program of NASA. This will be achieved through the use of a specially designed two-color holographic interferometry breadboard optical system. In addition to experiments to achieve the primary goals, the breadboard will also provide inputs to the design of an optimum space flight system. Author

HIGH COUNTING RATE RESISTIVE-PLATE CHAMBER

V. Peskov, D. F. Anderson, and S. Kwan May 1993 14 p

(Contract DE-AC02-76CH-03000)

(DE93-014928; FNAL-TM-1838) Avail: CASI HC A03/MF A01

Parallel-plate avalanche chambers (PPAC) are widely used in physics experiments because they are fast (less than 1 ns) and have very simple construction: just two parallel metallic plates or mesh electrodes. Depending on the applied voltage they may work either in spark mode or avalanche mode. The advantage of the spark mode of operation is a large signal amplitude from the chamber, the disadvantage is that there is a large

dead time (msec) for the entire chamber after an event. The main advantage of the avalanche mode is high rate capability 10(exp 5) counts/mm(sup 2). A resistive-plate chamber (RPC) is similar to the PPAC in construction except that one or both of the electrodes are made from high resistivity (greater than 10(exp 10) Omega(cm) materials. In practice RPC's are usually used in the spark mode. Resistive electrodes are charged by sparks, locally reducing the actual electric field in the gap. The size of the charged surface is about 10 mm(sup 2), leaving the rest of the detector unaffected. Therefore, the rate capability of such detectors in the spark mode is considerably higher than conventional spark counters. Among the different glasses tested the best results were obtained with electron type conductive glasses, which obey Ohm's law. Most of the work with such glasses was done with high pressure parallel-plate chambers (10 atm) for time-of-flight measurements. Resistive glasses have been expensive and produced only in small quantities. Now resistive glasses are commercially available, although they are still expensive in small scale production. From the positive experience of different groups working with the resistive glasses, it was decided to review the old idea to use this glass for the RPC. This work has investigated the possibility of using the RPC at 1 atm and in the avalanche mode. This has several advantages: simplicity of construction, high rate capability, low voltage operation, and the ability to work with non-flammable gases. DOE

QUALIFICATION TEST OF THE ROSS DOUBLE PLANETARY MIXER Final Report
Kurt F. Lueders Jul. 1993 24 p
(Contract NAS8-38100)
(NASA-CR-192600; NAS 1.26:192600; TWR-50222) Avail: CASI HC A03/MF A01

This test report describes the qualification test of the Ross Double Planetary Mixer used to mix room temperature vulcanized (RTV) silicone (Dow Corning 90-006-2) for the redesigned solid rocket motor (RSRM) nozzle joints. Testing was completed 18 June 1993 in the M-113A Nozzle Fabrication Facility at Thiokol Corporation, Space Operations, Brigham City, Utah. The Ross mixer provides better mixing and better control on temperature and humidity, resulting in better quality RTV and a longer usable pot life. The test began on 3 May 1993 and was stopped due to operator error during the tensile strength and elongation testing. Specimens were ruined without gathering any useful data. A 'no test' was declared, the problem was remedied, and the test was re-run with MSFC approval. The test was run and all pass/fail criteria were met, most with a considerable margin. The Ross Double Planetary Mixer met all certification objectives and is recommended for immediate use for mixing RTV silicone for RSRM nozzle joints. Author (revised)

(Contract DE-AC04-76DP-00789)
(DE93-013949; SAND-92-2816) Avail: CASI HC A03/MF A01 (US Sales Only)

A device to measure the velocity and to determine the character of a material launched in a flight tube during the execution of an experiment has been constructed. This measurement device provides a self generating signal, is nonintrusive, compact, and accurate. The signals are reproducible, and it is relatively inexpensive to procure. The MAgnetic Velocity Induction System (MAVIS) has been the technique used to measure projectile velocities in the two-stage light gas gun at Sandia for many years. Several experiments were conducted to study the MAVIS data signatures produced by various metal projectiles at velocities raging from 0.8 km/sec to nearly 7.0 km/sec, as well as fragmented metal projectiles, and a highly conductive carbon plasma. This report deals with the results of those calibration experiments. The data signature study may be used as an aid in the interpretation of the other test data records. DOE

VACUUM ULTRAVIOLET INSTRUMENTATION FOR SOLAR IRRADIANCE AND THERMOSPHERIC AIRGLOW Semiannual Report, FY 1993
Thomas N. Woods, Gary J. Rottman, Scott M. Bailey (Colorado Univ., Boulder.), and Stanley C. Solomon (Colorado Univ., Boulder.) 25 Aug. 1993 21 p
(Grant NAG5-676)
(NASA-CR-194525; NAS 1.26:194525) Avail: CASI HC A03/MF A01

A NASA sounding rocket experiment was developed to study the solar extreme ultraviolet (EUV) spectral irradiance and its effect on the upper atmosphere. Both the solar flux and the terrestrial molecular nitrogen via the Lyman-Birge-Hopfield bands in the far ultraviolet (FUV) were measured remotely from a sounding rocket on October 27, 1992. The rocket experiment also includes EUV instruments from Boston University (Supriya Chakrabarti), but only the National Center for Atmospheric Research (NCAR)/University of Colorado (CU) four solar instruments and one airglow instrument are discussed here. The primary solar EUV instrument is a 1/4 meter Rowland circle EUV spectrograph which has flown on three rockets since 1988 measuring the solar spectral irradiance from 30 to 110 nm with 0.2 nm resolution. Another solar irradiance instrument is an array of six silicon XUV photodiodes, each having different metallic filters coated directly on the photodiodes. This photodiode system provides a spectral coverage from 0.1 to 80 nm with about 15 nm resolution. The other solar irradiance instrument is a silicon avalanche photodiode coupled with pulse height analyzer electronics. This avalanche photodiode package measures the XUV photon energy providing a solar spectrum from 50 to 12,400 eV (25 to 0.1 nm) with an energy resolution of about 50 eV. The fourth solar instrument is an XUV imager that images the sun at 17.5 nm with a spatial resolution of 20 arc-seconds. The airglow spectrograph measures the terrestrial FUV airglow emissions along the horizon from 125 to 160 nm with 0.2 nm spectral resolution. The photon-counting CODACON detectors are used for three of these instruments and consist of coded arrays of anodes behind microchannel plates. The one-dimensional and two-dimensional CODACON detectors were developed at CU by Dr. George Lawrence. The pre-flight and post-flight photometric calibrations were performed at our calibration laboratory and at the Synchrotron Ultraviolet Radiation Facility (SURF) at the National Institute of Standards and Technology (NIST) in Gaithersburg, Maryland. SHIELDED OPEN-CIRCUITED SAMPLE HOLDERS FOR DIELECTRIC AND MAGNETIC MEASUREMENTS OF LIQUIDS AND POWDERS
J. Baker-Jarvis, M. D. Janezic, and R. B. Stafford (Virginia Polytechnic Inst. and State Univ., Blacksburg.) Mar. 1993 33 p
(PB93-198851; NISTIR-5001) Avail: CASI HC A03/MF A01

The report overviews shielded open-circuit measurements and presents a comprehensive uncertainty analysis. The authors use a dominant-mode scattering formulation to develop an expression for the reflection coefficient in terms of bead and sample parameters. The formulation developed here eliminates the transformation through the various sections of the sample holder. The authors also extend the formulation to include magnetic measurements. The uncertainty analysis indicates a decrease in relative uncertainty with increasing sample length and with increasing frequency. The real part of the permittivity at low frequencies is very sensitive to the measured phase of the reflection coefficient and the sample length. The imaginary part of the permittivity of low-loss materials is not extremely sensitive to the sample length. For high-loss materials both the real and the imaginary parts of the permittivity are sensitive to the sample lengths. NTIS

(DE93-013962; SAND-93-0645) Avail: CASI HC A03/MF A01 (US Sales Only)

Streak cameras operating in the image motion mode are widely used in the photo instrumentation field to measure the velocities of high-velocity projectiles. The larger format cameras are also capable of producing detailed photographs of high-velocity projectiles with virtually no image blur. Although the images produced by these cameras appear to be ordinary photographs, there are major differences that must be understood before any data reduction is undertaken. This report addresses the theory of operating streak cameras in the image motion mode, and the precautions that must be taken during image analysis. DOE

CONFOCAL PROFILOMETER WITH NANOMETRIC VERTICAL RESOLUTION
D. J. Butler, A. Horsfall, M. Hrynevych, P. D. Kearney, and K. A. Nugent 1992 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-622698; UM-P-92/51) Avail: CASI HC A03 (US Sales Only)

An optical system is described which is based on the method of Kobayashi et al. The instrument is capable of simultaneous confocal imaging and profilometry with nanometric (nm) vertical resolution. The profile is independent of the reflectivity of the sample and is obtained by raster-scanning the sample without active feedback. It is shown that the vertical resolution of this technique may be extended down to 1 nm and have recorded images with a resolution of better than 3 nm. The concept and design is considerably simpler than most optical profilometers and may represent the most affordable method of profilometry with nanometric resolution available. DOE

High power and radiance dye lasers developed at Lawrence Livermore National Laboratory show promise for material processing tasks. Evaluations using welding heat flow models suggests significant increases in precision and speed are expected. We started processing studies to determine the viability of these lasers for cutting and drilling. Titanium and stainless steel alloys were chosen as materials for the preliminary studies. Results show that cuts and holes with extremely fine features can be made with dye and copper-vapor lasers. High radiance beams produce low distortion and small heat affected zones. We have accomplished very high aspect ratios and micron scale kerfs and holes in both stainless steel and titanium alloys. DOE

THREE DIMENSIONAL TIME-DEPENDENT HYDRODYNAMIC AND PROPAGATION MODELING OF X RAY LASER EMISSION
R. P. Ratowsky, M. D. Feit, R. A. London, R. S. Walling, G. M. Shimkaveg, A. L. Osterheld, M. R. Carter, and R. S. Craxton Jun. 1992 5 p Presented at the 3rd International Colloquium on X Ray Lasers, Schliersee, Germany, 18-22 May 1992
(Contract W-7405-eng-48)
(DE93-012575; UCRL-JC-110000; CONF-920523-12) Avail: CASI HC A01/MF A01

We have carried out three dimensional time-dependent calculations of x-ray emission in exploding, foil-line, focus-produced plasmas relevant to neon-like yttrium experiments at the Lawrence Livermore National Laboratory (LLNL). Hydrodynamic simulations using LASNEX and a simple gain profile based on XRASER are input into CASER, which solves the radiation transport equation along three dimensional ray orbits. Experimental observables such as farfield patterns and x-ray signal vs. laser length are then computed and compared with experiment. Similar two dimensional calculations have also been performed using the wave optics code WAVE to calculate coherence and confirm the accuracy of the ray optics treatment. We have found good agreement between both experiment and simulation and between the ray and wave optics codes. DOE

EVOLUTION OF HIGH-REPETITION-RATE INDUCTION ACCELERATORS THROUGH ADVANCEMENTS IN SWITCHING
H. C. Kirbie, G. J. Caporaso, M. A. Newton, and S. S. Yu 20 Aug. 1992 7 p Presented at the 16th International LINAC Conference, Ottawa, Ontario, 23-28 Aug. 1992
(Contract W-7405-eng-48)
(DE93-012599; UCRL-JC-110213; CONF-9208109-88) Avail: CASI HC A02/MF A01

Future applications of linear and recirculating induction accelerators include microwave sources for plasma heating and linear colliders, industrial manufacturing processes, and heavy ion fusion. These applications require pulsed sources capable of sustained operation at high pulse-repetition rates. Powering these new accelerators places severe switching demands on the source, demands that often can not be met withcommercially-available technology. Consequently, several new accelerator switching schemes have been developed at Lawrence Livermore National Laboratory (LLNL). Our transition from spark-gap technology to magnetic switching has merged the formerly independent roles of source and cell into a single system and reshaped our design methods to emphasize high efficiency. Treatment of the accelerator as a system has also enabled us to optimize new accelerator designs based on cost considerations. Presently, we are developing a technology for driving a heavy-ion induction recirculator at pulse rates exceeding 100 kHz. In this case, the switching method is all solid state and the source and cell have evolved into a unified device. DOE

KINETIC STUDIES FOLLOWING STATE-SELECTIVE LASER EXCITATION
J. W. Keto Oct. 1992 44 p
(Contracts DE-FG05-84ER-13191; DE-FG03-93ER-14348)
(DE93-012970; DOE/ER-13191/13) Avail: CASI HC A03/MF A01

Measurements of state-to-state deactivation cross sections and radiative lifetimes were made for Xe*(6p,6p',7p) and Kr*(5p) states in xenon and krypton buffer gases. These results are relevant to kinetic models of both excimer lasers and the infrared xenon laser. Attempts were made to continue studies of two-photon laser assisted collisions in the reaction Xe + Cl2 + (Dirac h)(omega) yields (Xe(+)(circ)Cl2(-)) yields XeCl*(high v) + Cl. These experiments along with studies of the XeCl*(B, C, and D) branching fractions are reported along with studies of the two-photon spectroscopy of Cl2. In addition, significant progress was made in the study of the spectroscopy of small molecules and excimers formed in supersonic beams. Although emphasis is on xenon excimers excited in two-photon transitions, larger rare gas clusters were measured. Splitting between the 2s and 2p excitons is not explainable by currently accepted models for excitons in liquid xenon. Finally, work to obtain fluorescent spectra of xenon excimers in supersonic jets is described. DOE

This report summarizes the progress and accomplishments of this research project from 1 Sep. 1989 to 28 Feb. 1993. During this period, we have accomplished all of the primary scientific objectives of the research proposal: (1) constructed and evaluated a laser-induced fluorescence detection system that allows direct examination of the chromatographic column, (2) examined nonequilibrium processes that occur upon solute injection and elution, (3) examined solute retention in liquid chromatography as a function of temperature and pressure, (4) examined solute zone dispersion in liquid chromatography as a function of temperature and pressure, and (5) developed appropriate theoretical models to describe these phenomena. In each of these studies, substantial knowledge has been gained of the fundamental processes that are responsible for chromatographic separations. In addition to these primary research objectives, we have made significant progress in three related areas: (1) examined pyrene as a fluorescent polarity probe in supercritical fluids and liquids as a function of temperature and pressure, (2) developed methods for the class-selective identification of polynuclear aromatic hydrocarbons in coal-derived fluids by microcolumn liquid chromatography with fluorescence quenching detection, and (3) developed methods for the determination of saturated and unsaturated (including omega-3) fatty acids in fish oil extracts by microcolumn liquid chromatography with laser-induced fluorescence detection. In these studies, the advanced separation and detection techniques developed in our laboratory are applied to practical problems of environmental and biomedical significance. DOE

This work strives to develop high average power FEL's at voltages below I MV allowing for smaller and less costly power supplies. To achieve operation of an FEL with 100 GHZ (approx It) f (approx It) 150 GHz and with relatively modest voltage, we have been investigating the use of small period ((lambda)(sub (omega)) (approximately) 1 cm) planar wiggler magnets together with sheet electron beams. The sheet beam geometry allows for an FEL interaction region in the form of a narrow slit with high wiggler field at the center plane where the electrons are concentrated. The total current and power may then be increased without making current density excessive by increasing the wide dimension of the sheet beam. Sheet beam FEL design parameters for both a Proof-of-Principle (PoP) FEL experiment, which is current in progress, and an ITER relevant FEL design are shown. A central issue in the sheet beam FEL concept is propagation of the beam through the interaction region without excessive interception by the walls. In section 2 below we describe a successful experimental demonstration of sheet beam propagation through a 56 period uniform wiggler. Cold testing and initial hot test operation of the (PoP) FEL amplifier are also described. Finally, we present a theoretical investigation of the bandwidth of an FEL amplifier with a tapered wiggler operating in saturation is described. DOE

NOVEL Co:MgF2 LIDAR FOR AEROSOL PROFILER Final Report
M. A. Acharekar Sep. 1993 44 p Original contains color illustrations
(Contract NAS1-19300)
(NASA-CR-191525; NAS 1.26:191525) Avail: CASI HC A03/MF A01; 2 functional color pages

Lidars are of great interest because of their unique capabilities in remote sensing applications in sounding of the atmosphere, meteorology, and climatology. In this small business innovative research (SBIR) phase II program, laser sources including Co:MgF2, CTH:YAG, CTH:YSGG, CT:YAG, and Er:Glass were evaluated. Modulator of fused silica and TeO2 materials with Brewster's angle end faces were used with these lasers as acousto-optical (AO) Q-switches. A higher hold-oif energy and hence a

higher Q-switched energy was obtained by using a high power RF driver. The report provides performance characteristics of these lasers. The tunable (1.75-2.50 microns) Co:MgF2 laser damaged the TeO2 Q-switch cell. However, the CTH:YAG laser operating at 2.09 microns provided output energy of over 300 mJ/p in 50 ns pulse width using the fused silica Q-switch. This Q-switched CTH:YAG laser was used in a breadboard vertical aerosol profiler. A 40 cm diameter telescope, InSb and InGaAs detectors were used in the receiver. The data obtained using this lidar is provided in the report. The data shows that the eye safe lidar using CTH:YAG laser for the vertical aerosol density and range measurements is the viable approach. Author (revised)

PREDICTED PERFORMANCE OF A DC BEAM DRIVEN FEM OSCILLATOR DESIGNED FOR FUSION APPLICATIONS AT 200-250 GHz
M. Caplan, R. W. B. Best, A. G. A. Verhoeven, M. J. VanderWiel, W. H. Urbanus, V. L. Bratman, and G. G. Denisov 21 Aug. 1992 22 p Presented at the 14th International Free Electron Laser Conference, Kobe, Japan, 23-28 Aug. 1992
(Contract W-7405-eng-48)
(DE93-013414; UCRL-JC-111690; CONF-9208142-22) Avail: CASI HC A03/MF A01

A Free Electron Laser (FEL) using a DC beam with a depressed collector is being developed at the FOM Institute (Netherlands) for plasma heating. The FEL will be capable of producing 1 MW CW output over an adjustable tuning range of 200-250 GHz. The basic design parameters for the electron beam, undulator, and waveguide circuit are determined using a 3D non-wiggle averaged waveguide mode particle interaction code including AC space charge effects. Novel features of the design include using a step tapered two section wiggler to achieve both the high gain (10) and the required efficiency (approximately 5%) as well as a rectangular corrugated HE(sub 11) waveguide circuit to handle the high average power requirements. Results are presented on FEM performance including dependence on beam emittance, percent feedback, and operating frequency. DOE

ABSORPTION AND DAMAGE THRESHOLDS OF LOW DEFECT DENSITY HAFNIA DEPOSITED WITH ACTIVATED OXYGEN
R. Chow, S. Falabella, G. E. Loomis, F. Rainer, C. J. Stolz, and M. R. Kozlowski Oct. 1992 16 p Presented at the Laser-Induced Damage in Optical Materials, Boulder, CO, 28-30 Oct. 1992
(Contract W-7405-eng-48)
(DE93-013853; UCRL-JC-111458; CONF-9210356-1) Avail: CASI HC A03/MF A01

Motivation for this work included observations of a correlation between increasing laser damage thresholds and both decreasing nodular-defect density and absorption of coatings. We reduced the nodular-defect densities by a factor of over 4x in hafnia coatings deposited by reactive e-beam evaporation from a Hf target source. In order to increase the metal oxidation kinetics at the coated surface, Hf was e-beam deposited reactively with oxygen activated by a (mu)-wave discharge. The effect of using activated oxygen during the evaporation of a hafnia target source was also evaluated. A series of hafnia layers were made with various conditions; we alternated between two (mu)-wave configurations, hafnium and hafnia targets and two reactive oxygen pressures. Laser damage thresholds (1064 nm -10 ns pulses), absorption (at 511 nm) and nodular-defect densities from these coatings are reported. The damage threshold correlated inversely with the coating absorption. DOE

Imaging microscopy with short pulse (200 ps) x-ray lasers offers the opportunity of high resolution three-dimensional imaging of specimens in an aqueous environment without the blurring effects associated with natural motion. As a first step towards this goal we have performed imaging experiments which clearly resolved 500 A features on a gold test pattern. In addition, we have taken images of dried biological specimens as a basis for comparison in future wet specimen imaging. Results of these experiments will be described. We also discuss some of the alignment problems involved in doing x-ray microscopy with low rep rate systems where in situ focusing of the imaging optics is not practical as single shot exposures can alter the specimen. Laboratory x-ray lasers are currently being developed by researchers worldwide as potential sources for x-ray imaging and other applications. Laser action has been demonstrated at wavelengths as short as 35.6 A, and there is a large effort underway to enhance the coherent power output of the Ni-like Ta x-ray laser at 44.83 A as a source for x-ray imaging of live cells. Part of this effort is dedicated to producing a more affordable, compact laser to pump the x-ray laser in order to increase the accessibility of x-ray laser sources. DOE

A scannerless LAser Detection And Ranging (LADAR) system is presently under development for applications at Sandia National Laboratories. This LADAR design eliminates the need for a mechanical laser beam scanner which is often the system component that limits the use of laser radars for many applications. Range to the target scene is determined in this approach by measuring the phase shift of the intensity modulation on the received optical return compared to the reference. The approach used in this LADAR is unique because the method used to detect this phase shift is an array of time integrating detectors that also records the image of the target scene. An analytical model will be presented that describes the LADAR system performance. Applications of this LADAR system will also be reviewed. The applications include terminal guidance of advanced conventional munitions, perimeter surveillance of secure facilities, mapping potholes/cracks in the US highway system for improved maintenance scheduling, active collision avoidance of commercial/private vehicles, robotic vision integrated into advanced manufacturing concepts, and a novel airborne multi-sensor system containing LADAR, SAR, and LIDAR to locate and measure the thickness of ocean oil spills. SHOCK-FREE ACCELERATION OF LASER DRIVEN TARGETS
10 Dec. 1992 15 p
(Contract DE-AI03-79DP-40092)
(DE93-008050; NRL/MR-6440-92-7170) Avail: CASI HC A03/MF A01 (US Sales Only)

The ability of recently developed laser smoothing techniques to produce uniform ablation pressures is strongly contingent on the degree of thermal smoothing. Thermal smoothing is not effective at reducing residual laser nonuniformities during the start up phase of a shaped, reactor-like laser pulse. The impact of the first shock can be diminished by adiabatically compressing the target with a temporally long, slowly rising laser pulse. This Memorandum Report discusses an elastic-plastic laser-matter-interaction model and shows that a shock-free, induced spatial incoherence-smoothed

laser pulse can accelerate a target to nearly the conditions required for uniform implosion. Author

Work on the development of an interferometric system for the purpose of absolute length determination commenced in January of this year. Our goal is to develop a system capable of measurements on the order of one meter with an accuracy of 1 part in 10 or greater. A modified Michelson bread board with stabilized laser diode source was assembled. Some preliminary measurements began using the tunable Santek laser in an FM modulation scheme. During this same period a literature search yielded a paper by Suematsu and Takeda which discusses a promising fourier transform technique for real time data analysis. We are in the process of evaluating this technique while we continue to change and upgrade the system configuration. Author (revised)

(DE93-012571; UCRL-JC-109276; CONF-920792-57) Avail: CASI HC A03/MF A01

This paper describes the design and performance of an automated, closed-loop, laser beam alignment system. Its function is to sense a beam alignment error in a laser beam transport system and automatically steer mirrors preceding the sensor location as required to maintain beam alignment. The laser beam is sampled by an optomechanical package which uses video cameras to sense pointing and centering errors. The camera outputs are fed to an image processing module, which includes video digitizers and uses image storage and software to sense the centroid of the image. Signals are sent through a VMEbus to an 'optical device controller' (ODC), which drives stepper-motor actuators on mirror mounts preceding the beam-sampling location to return the beam alignment to the prescribed condition. Photodiodes are also used to extend the control bandwidth beyond that which is achievable with video cameras. This system has been operated at LLNL in the Atomic Vapor Laser Isotope Separation (AVLIS) program to maintain the alignment of copper and dye laser beams, the latter to within +/- 2 micro-r in pointing and less than 1 mm in centering. The optomechanical design of the instrumented package, which includes lens, mirror, and video mounts in a rigid housing, the automated control system architecture, and the performance of this equipment is described. CHARACTERISTICS OF SEMICONDUCTOR LASERS WITH OPTICAL FEEDBACK Ph.D. Thesis
Jann Oluf Binder 1989 221 p
(ISBN-0-315-55435-5; CTN-93-60721) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

Discrete optical and fiber optic components were used along with a semiconductor diode to create both Fabry-Perot and ring-type external cavity lasers. The number of external cavity modes (ECM's) and the distribution of power in those modes in the weak optical feedback domain were studied. In the ECM, oscillation with minimum linewidth was observed and agreed with a frequency fluctuation model. The upper limit of stable operation in the weak feedback domain and the tradeoff between minimum linewidth and minimum number of ECM's is discussed. An optimized fiber-ring feedback assembly was observed to reduce the linewidth drastically and provide over 20 dB of suppression of ECM side modes. In the strong optical feedback domain, large changes in the carrier density and changes in the gain and resonance frequency of the cavity occurring due to injection of light were analyzed. A model is presented for the experimentally observed bistability and tuning range of an external grating laser, the effect of residual reflectivity on tuning characteristics, and the change of threshold current with resonator loss. The light versus current characteristic and spectral properties of a unidirectional semiconductor optical fiber ring laser were also investigated. Author (CISTI)

LASER CO2 BEAM TRANSMISSION THROUGH HOLLOW METALLIC WAVEGUIDE COATED BY A THIN INTERNAL DIELECTRIC LAYER M.S. Thesis
Thierry Boutboul Apr. 1991 164 p In HEBREW
(ITN-93-85201) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

The CO2 laser, which is the most commonly used laser in medicine, is usually restricted to external use, owing to the lack of a waveguide suitable for transmitting its radiation. It has been proposed to solve this problem by using a hollow metallic waveguide with an internal dielectric coating, since air is a quasi-transparent medium for radiation of wavelength 10.6 micron. The potential contribution of a dielectric layer has been proved both experimentally and theoretically. A theoretical model was developed, based on wave theory and Maxwell's equations, to compute laser beam transmission through a waveguide of this type. Based on knowledge of the waveguide inlet fields, it was possible to compute the radiation power density at each point on the waveguide outlet plane. The model uses the fact that the tangential field components on the metallic boundary cancel, in order to develop the longitudinal components into a Fourier-Bessel series when all the computations were done on the Laplace plane. The transverse components could be expressed as a function of the longitudinal components on the Laplace plane. Laplace inverse transform computation enabled the transverse components on the real plane and the power density at each point at the outlet to be computed. The theoretical model was applied to a silver waveguide with a thin coating of silver iodide, taking account of the transition region between the different materials. ISA

HORIZONTAL-CAVITY SURFACE-EMITTING LASERS, SUPERLUMINESCENT LEDs, AND AMPLIFIERS, AND PARABOLIC GAIN UNSTABLE RESONATOR SEMICONDUCTOR LASERS Ph.D. Thesis
Dennis Patrick Bowler 1992 234 p
Avail: Univ. Microfilms Order No. DA9310956

Two separate but related problems are addressed in this dissertation. The first is concerned with the transverse mode of folded-cavity devices (e.g. HC SELs, SLEDs, amplifiers) containing an intracavity 45 degree mirror. These devices are conducive to large scale cost effective fabrication and high power operation. The second problem is lateral mode control of broad area lasers using gain tailored unstable resonators. A beam propagation model for folded-cavity devices is presented which includes Fresnel reflections from multilayer thin-films, angular errors in the 45 degree micromirror, the dependence on the horizontal reflector separation, Fresnel beam propagation, and waveguide coupling losses of the reflected field. There is excellent agreement with experimental data for horizontal-cavity surface-emitting lasers (HC SELs) when scattering losses are included. Folded-end mirror performance can be improved by tilting the micromirror slightly toward normal incidence. Superluminescent light emitting diodes (SLEDs) and optical amplifiers are analyzed. Antireflection substrate coatings can improve performance significantly. Half-symmetric parabolic gain unstable resonator semiconductor lasers (URSLs) with Hermite-Gaussian lateral eigenmodes promise high power diffraction limited performance. Devices employing half-tone (HT) and lens-train (LT) electrode patterns are analyzed and fabricated. The HT electrode pattern promises better performance as compared to the LT approach. Although, the LT design which is more tolerant of processing variations, performed better than the HT approach, in this research. The parabolic gain URSLs appear to have significantly better lateral mode control under continuous wave (cw) operation than comparable rectangular stripe devices. A single lateral mode output of one watt cw was achieved with a LT parabolic gain URSL. Author

THEORETICAL INVESTIGATION OF SCATTERING BY HOMOGENEOUS OR COATED DIELECTRIC SPHERES ILLUMINATED WITH A STEADY STATE OR PULSED LASER BEAM Ph.D. Thesis
Elsayed Esam M. Khaled 1993 170 p
Avail: Univ. Microfilms Order No. DA9311980

A method of calculating the internal and scattered electric fields of a sphere illuminated with a Gaussian beam is presented. The vector nature of the beam is considered. The beam can be located arbitrarily with respect to the object. The method uses the angular spectrum of plane waves technique and the T-matrix method. This combination is used to investigate the scattering behavior of homogeneous and coated spheres. The electric energy in a lossless or lossy homogeneous spherical particle illuminated with a plane wave or a Gaussian beam is investigated. The amount of energy coupling into the particle for different beam illuminations is also investigated. Modes having high-Q morphology dependent resonances (MDR) can dominate the internal energy distribution in lossless or lossy spheres even when they are excited many line widths from the resonant location. This dominance of the high-Q mode increases when the beam is shifted farther away from the sphere. The effects of the absorption on the dominance of the internal fields by a high-Q mode decreases as the beam is shifted farther away from the particle. Although the coupled energy decreases as the beam is shifted farther from the sphere, most of that energy is in the lowest-order mode. Internal and scattered time-dependent intensities are calculated for a homogeneous dielectric sphere illuminated with a pulsed Gaussian beam. The center frequency of the pulse spectrum is chosen to be on, near, or far away from a morphology-dependent resonance of the sphere. The center of the beam is positioned inside, on the edge, or outside the sphere. Two different decay rates in the internal and scattered time dependent intensity are observed: a decay rate that depends on the incident pulse spectrum and a rate which depends on the line shape of the resonant mode of the sphere. The intensity of scattered fields by a coated sphere illuminated with an on- or off-axis Gaussian beam is calculated. As the beam is shifted farther away from the surface of the sphere, the higher-Q morphology dependent resonances become increasingly important in the backscatter spectra, and the angular scattering intensity becomes smoother. As the beam is moved farther away from the sphere, the effect of the core on the scattering intensity decreases. When the incident Gaussian beam is focused outside of a particle with a relatively small core, the scattering spectra and angular scattering patterns become similar to those of a homogeneous sphere having the refractive index of the coat. SINGLE EVENT EFFECTS AND LASER SIMULATION STUDIES
Q. Kim, H. Schwartz, K. McCarty, J. Coss, and C. Barnes 15 Aug. 1993 24 p
(Contract NAS7-918)
(NASA-CR-194506; JPL-Publ-93-23; NAS 1.26:194506) Avail: CASI HC A03/MF A01

The single event upset (SEU) linear energy transfer threshold (LETTH) of radiation hardened 64K Static Random Access Memories (SRAM's) was measured with a picosecond pulsed dye laser system. These results were compared with standard heavy ion accelerator (Brookhaven National Laboratory (BNL)) measurements of the same SRAM's. With heavy ions, the LETTH of the Honeywell HC6364 was 27 MeV-sq cm/mg at 125 C compared with a value of 24 MeV-sq cm/mg obtained with the laser. In the case of the second type of 64K SRAM, the IBM640ICRH no upsets were observed at 125 C with the highest LET ions used at BNL. In contrast, the pulsed dye laser tests indicated a value of 90 MeV-sq cm/mg at room temperature for the SEU-hardened IBM SRAM. No latchups or multiple SEU's were observed on any of the SRAM's even under worst case conditions. The results of this study suggest that the laser can be used as an inexpensive laboratory SEU prescreen tool in certain cases.

DESIGN AND PERFORMANCE OF THE TERAWATT Cr:LiSrAlF6 LASER SYSTEM
T. Ditmire, H. Nguyen, S. Herman, and M. D. Perry 28 Jan. 1993 22 p
(Contract W-7405-eng-48)
(DE93-014678; UCRL-ID-113182) Avail: CASI HC A03/MF A01

The authors have developed a compact, flashlamp-pumped Cr:LiSrAlF6 laser system capable of producing peak powers in excess of one terawatt. The chirped pulse amplification approach has been optimized for amplification of femtosecond pulses in Cr:LiSrAlF6. The system includes a Cr:LiSAF regenerative amplifier followed by a Cr:LiSAF power amplifier chain. The regenerative amplifier produces 12 mJ pulses at a 5 Hz repetition rate which are further amplified to energies above 300 mJ at a 0.5 Hz repetition rate. Recompression results in a pulse energy of 150 mJ and pulse duration of under 135 fsec.

NUMERICAL SIMULATIONS OF Nd:YAG LASER AMPLIFIERS
Halvor Ajer, Stig Landroe, and Knut Stenersen 12 Oct. 1992 45 p
(FFI/RAPPORT-92/7028; ETN-93-93974) Avail: CASI HC A03/MF A01

Numerical simulations of Nd:YAG amplifiers are presented. The simulations are based on a rate equation model which correctly accounts for the lower laser level decay rate. A model for single pass amplification of fluence (energy per area) for arbitrary temporal behavior of the input pulse is developed. By use of reasonable approximations, this model is applicable to double pass amplification of Q switched pulses. The coupled differential equations of the system are solved numerically by using the programs SIMNON and MATLAB. General examples of amplification of fluence are first presented, including investigation of the influence of the lower level lifetime. Amplification of a Gaussian transverse fluence distribution incident on an amplifier rod with uniform gain is then presented. A diode laser pumped rod amplifier is simulated (single and double pass) assuming a Gaussian input distribution; diffraction effects are addressed for this example.

CONSTRUCTION AND TEST OF A FACILITY FOR PHOTON-STIMULATED FIELD DESCRIPTION USING EXCIMER LASER AND TIME OF FLIGHT Ph.D. Thesis [AUFBAU UND TEST EINER ANORDNUNG ZUR PHOTONENSTIMULIERTEN FELDDESORPTION MITTELS EXCIMERLASER UND FLUGZEITMASSENSPEKTROMETRIE]
Sun-Dal Song 1992 108 p In GERMAN
(ETN-93-94386) Avail: CASI HC A06/MF A02

A facility for examination of solid bodies surface, based on photon desorption and ionization in the electric field, is developed. A pulse excimer laser with raman shifter and vacuum monochromator was used as radiation source in order to bring different light wavelengths, such as Stokes and anti Stokes lines, with high intensity to a field emitter point. Desorpted species were detected using time of flight mass spectrometry with a transient recorder, which allows ion spectrum to be recorded independently of ion number; emitter surface structure was simultaneously observed in atomic resolution with a field ion microscope. Several absorbates such as NO, He, and H2 were examined on tungsten at 80K, with several wavelengths and field intensities to establish apparatus functionality. The influence of NO gas pressure and photon energy on mass spectrum was studied.

STUDY OF SPECKLE REDUCTION WHEN USING A CO2 WAVEGUIDE LASER CLOSE TO ITS THRESHOLD STATE
Michel Morin, Bruno Labranche, and Pierre Bernard Dec. 1992 41 p
(Contract DSS-W7702-1-R289-01-XSG)
(DSIS-93-00250; DRES-CR-4-93; INO-92-5102; CTN-93-60803) Avail: CASI HC A03

Experiments were conducted with a CO2 metallic waveguide laser to determine whether the coherence of the laser, a source of interest for

active infrared imaging systems, can be reduced by near-threshold operation. The study also evaluated the impact of such a procedure on the other laser properties and the speckle contrast reduction from this coherence decrease. Analysis indicates that coherence reduction through near-threshold operation is not a viable approach with the type of laser used. The strength of the spontaneous emission is insufficient and non-radiative processes quench the population inversion without allowing any significant extraction of energy through radiation. Experimentally, attempts to operate the laser at output powers below 0.4 W led to extinction of the beam, with no measurable radiative power coming out of the waveguide. Procedures for generation and detection of speckle patterns on a depolished aluminum plate with a CO2 laser were established and verified. All measurements were found to be consistent with theory. No contrast reduction was observed, which could be linked to a degradation of the coherence of the laser.

Laser ablation particle plume compositions are characterized using inductively coupled plasma/mass spectrometry (ICP/MS). This study evaluates the mass response characteristics peculiar to ICP/MS detection as a function of laser fluence and frequency. Evaluation of the ICP/MS mass response allows deductions to be made concerning how representative the laser ablation produced particle plume composition is relative to the targeted sample. Using a black glass standard, elemental fractionation was observed, primarily for alkalis and other volatile elements. The extent of elemental fractionation between the target sample and the sampled plume varied significantly as a function of laser fluences and IR and UV laser frequency. DOE

LASER BEAM CONTROL AND DIAGNOSTIC SYSTEMS FOR THE COPPER-PUMPED DYE LASER SYSTEM AT LAWRENCE LIVERMORE NATIONAL LABORATORY
E. S. Bliss, R. L. Peterson, J. T. Salmon, and R. A. Thomas Nov. 1992 17 p Presented at the OE/LASE 1993 International Society for Optical Engineering Conference, Los Angeles, CA, 16-23 Jan. 1993
(Contract W-7405-eng-48)
(DE93-016529; UCRL-JC-112671; CONF-930159-41) Avail: CASI HC A03/MF A01

The laser system described in the previous paper is used for experiments in which success requires tight tolerances on beam position, direction, and wavefront. Indeed, the optimum performance of the laser itself depends on careful delivery of copper laser light to the dye amplifiers, precise propagation of dye laser beams through restricted amplifier apertures, and accurate monitoring of laser power at key locations. This paper describes the alignment systems, wavefront correction systems, and laser diagnostics systems which ensure that the control requirements of both the laser and associated experiments are met. Because laser isotope separation processes utilize more than one wavelength, these systems monitor and control multiple wavelengths simultaneously. DOE

MICROCHANNEL COOLED HEATSINKS FOR HIGH AVERAGE POWER LASER DIODE ARRAYS
W. J. Bennett, B. L. Freitas, D. Ciarlo, R. Beach, S. Sutton, M. Emanuel, and R. Solarz 15 Jan. 1993 12 p Presented at the OE/LASE 1993: International Society for Optical Engineering (SPIE) Conference, Los Angeles, CA, 16-23 Jan. 1993
(Contract W-7405-eng-48)
(DE93-016533; UCRL-JC-112678; CONF-930159-42) Avail: CASI HC A03/MF A01

Detailed performance results for an efficient and low impedance laser diode array heatsink are presented. High duty factor and even CW operation of fully filled laser diode arrays at high stacking densities are enabled at high average power. Low thermal impedance is achieved using a liquid coolant and laminar flow through microchannels. The microchannels are fabricated in silicon using an anisotropic chemical etching process. A modular rack-and-stack architecture is adopted for heat sink design, allowing arbitrarily large two-dimensional arrays to be fabricated and easily maintained. The excellent thermal control of the microchannel heatsinks is ideally suited to pump army requirements for a high average power crystalline laser because of the stringent temperature demands that are required to efficiently couple diode light to several-nanometer-wide absorption features characteristic of lasing ions in crystals. ADIABATIC AND NON ADIABATIC EFFECTS IN FREE ELECTRON LASER (FEL) NON LINEAR INTERACTIONS Ph.D. Thesis
Zvi Sheena Aug. 1990 167 p
(ITN-93-85224) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

This work describes the theoretical and experimental research performed in order to study adiabatic and non-adiabatic effects in FEL interactions in the non-linear regime. The research was based on a scheme in which a non-relativistic electron beam interacts with the ponderomotive field (beat wave) resulting from two counter-propagating TEA CO2 laser beams operating at different frequencies in a simulated Compton scattering scheme. A mathematical model was built and then used to study and to develop several adiabatic and non-adiabatic interaction schemes. A final scheme that can simulate both types of interaction was chosen. In this scheme the electron beam can interact adiabatically with the ponderomotive wave using a circular or a slanted entry path to cause the electrons to be trapped by the wave and to travel at its phase velocity along a linear path, to produce what is called a phase area displacement type of interaction, in which the electrons follow open trajectories in the phase-space diagram. The electron beam can also interact non-adiabatically with the ponderomotive wave, using an abrupt shift in the energy of the electrons to produce efficient trapping. An experimental setup that physically simulates these interaction schemes was constructed. Using this setup, experiments were conducted to investigate the energy exchange relationships between the electrons and the ponderomotive wave. The experimental results revealed that efficient electron trapping can be obtained using an abrupt shift in their energy in order to bring them into resonance with the ponderomotive wave. Generation of femtosecond pulses from a continuous-wave mode-locked chromium-doped forsterite (Cr(4+):Mg2SiO4) laser has been accomplished. The forsterite laser was actively mode-locked using an acousto-optic modulator operating at 78 MHz with two Brewster high-dispersion glass prisms for intra-cavity chirp compensation. Transform-limited sub-100-fs pulses were routinely generated in the TEM(sub 00) mode with 85 mW of continuous power (with 1 percent output coupler), tunable over 1230-1280 nm. The shortest pulses of 60-fs pulsewidth were measured. Derived from text

(DE93-016532; UCRL-JC-112624; CONF-930159-43) Avail: CASI HC A02/MF A01

Recent progress in the understanding of high-order harmonic conversion from atoms and ions exposed to high-intensity, short-pulse optical lasers is reviewed. We find that ions can produce harmonics comparable in strength to those obtained from neutral atoms, and that the emission extends to much higher order. Simple scaling laws for the strength of the harmonic emission and the maximum observable harmonic are suggested. These results imply that the photoemission observed in recent experiments in helium and neon contains contributions from ions as well as neutrals. DOE

Batson (California Univ., Berkeley. Lawrence Berkeley Lab.) 1 Mar. 1993 8 p Presented at the 1992 International Conference on Lasers, Houston, TX, 7-11 Dec. 1992
(Contracts W-7405-eng-48; DE-AC03-76SF-00098)
(DE93-016543; UCRL-JC-113290; CONF-921256-5) Avail: CASI HC A02/MF A01

The authors discuss their recent measurements of the spectral width of the 206.38 Angstrom x-ray laser transition in Ne-like Se. These measurements used a high-resolution grating spectrometer and were performed over a wide range of laser amplifier lengths. The data have enabled them to extrapolate the intrinsic line width and to observe the effects of gain-narrowing and saturation on the line profile. They find an intrinsic width which is 1.4 times the Doppler width, they observe gain-narrowing in intermediate length amplifiers, and they observe no re-broadening in long, saturated amplifiers. These results suggest that collisional line-broadening has a significant effect on the line profile and saturation behavior of this laser. DOE

AlGaAs DIODE LASER BLUE SHIFT RESULTING FROM FAST NEUTRON IRRADIATION
J. C. Camparo, S. B. Delcamp, and R. P. Frueholz 10 Nov. 1992 36 p
(Contract F04701-88-C-0089)
(AD-A266642; TR-0091(6925-13)-2; SMC-TR-93-27) Avail: CASI HC A03/MF A01

Six TJS (transverse junction stripe) AlGaAs diode lasers were exposed to fast neutrons with fluences ranging from 2 x 10(exp 12) to 3 x 10(exp 13) n/sq cm, and their tuning, gain, and dispersion curves were measured. The tuning and gain curves of four lasers showed blue shifts of several meV at neutron fluences as low as 2 x 10(exp 12) n/sq cm, the other two lasers never showed this blue shift. In addition, the lasers that displayed a blue shift also showed an increase in their threshold currents. None of the lasers exhibited any change in their dispersion curves. To explain the blue shift, it is hypothesized that neutron irradiation reduces the efficiency for lasing in the bandtail states of these devices, forcing lasing action to occur between states with greater energy separation. A model in which the reduced efficiency takes the form of a decrease in the transition matrix element is found to yield blue shifts of the correct order of magnitude. Though bandtail effects may also explain the difference in radiation sensitivity

among the TJS lasers, at present the reason why only four of the six lasers blue shifted after neutron irradiation is not well understood. DTIC

LASER LITHOGRAPHY BY PHOTON SCANNING TUNNELING MICROSCOPY
I. Lee, R. J. Warmack, and T. L. Ferrell 1993 6 p Presented at the 2nd International Conference on Laser Ablation: Mechanisms and Applications, Knoxville, TN, 19-22 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015962; CONF-9304144-8) Avail: CASI HC A02/MF A01

We have investigated the possibility of using a photon scanning tunneling microscope (PSTM) for laser lithography. A contrast enhancement material (CEM) is coated onto a sample slide and coupled to the prism of a PSTM. The CEM becomes transparent above a laser (HeCd at a wavelength of 442 nm) intensity threshold attained due to the proximity of the probe tip. The same surface can then be inspected using the given experimental configuration by replacing the HeCd laser line with a non-exposing 633-nm HeNe laser line. Direct patterns can be produced by varying the exposure time and the shape of the probe tip. DOE

OPTIMIZATION STUDY OF X RAY LASER COHERENCE IN Ni-LIKE Ta
P. Amendt, R. A. London, and M. Strauss (Israel Atomic Energy Commission, Beersheba.) Jun. 1993 6 p Presented at the 3rd International Colloquium on X Ray Lasers, Schliersee, Germany, 18-22 May 1992
(Contract W-7405-eng-48)
(DE93-016419; UCRL-JC-110084; CONF-920523-16) Avail: CASI HC A02/MF A01

By separately employing a wave optics treatment based on a modal expansion of the laser electric field and ray optics methods, criteria are proposed which serve to optimize transverse coherence. Refraction is shown to increase the saturation gain-length of the laser, thereby enabling a higher coherent energy output. Under optimum conditions the calculated output for a single stage Ni-like Ta x-ray laser of nearly one mJ in 100 psec from a single stage Ni-like Ta x-ray laser may be satisfactory for 300 A resolution holographic imaging of biological specimens. Conceptual designs were developed for the determination of rotordynamic coefficients of cryogenic fluid film bearings. The designs encompassed the use of magnetic and conventional excitation sources as well as the use of magnetic bearings as support bearings. Test article configurations reviewed included overhung, floating housing, and fixed housing. Uncertainty and forced response analyses were performed to assess quality of data and suitability of each for testing a variety of fluid film bearing designs. Development cost and schedule estimates were developed for each design. Facility requirements were reviewed and compared with existing MSFC capability. The recommended configuration consisted of a fixed test article housing centrally located between two magnetic bearings. The magnetic bearings would also serve as the excitation source. Author

Two single axis planetary roller-gear drives and a two axis roller-gear drive with dual inputs were designed for use as robotic transmissions. Each of the single axis drives is a two planet row, four planet arrangement with spur gears and compressively loaded cylindrical rollers acting in parallel. The two axis drive employs bevel gears and cone rollers acting in parallel. The rollers serve a dual function: they remove backlash from the system, and they transmit torque when the gears are not fully engaged.

LOW PRESSURE STORAGE OF NATURAL GAS ON ACTIVATED CARBON
J. Wegrzyn, H. Wiesmann, and T. Lee 1992 11 p Presented at the 1992 Annual Automotive Technology Development Contractors' Coordination Meeting (ATD/CCM), Dearborn, MI, 2-5 Nov. 1992
(Contract DE-AC02-76CH-00016)
(DE93-014053; BNL-48685; CONF-9211240-1) Avail: CASI HC A03/MF A01

The introduction of natural gas to the transportation energy sector offers the possibility of displacing imported oil with an indigenous fuel. The barrier to the acceptance of natural gas vehicles (NGV) is the limited driving range due to the technical difficulties of on-board storage of a gaseous fuel. In spite of this barrier, compressed natural gas (CNG) vehicles are today being successfully introduced into the market place. The purpose of this work is to demonstrate an adsorbent natural gas (ANG) storage system as a viable alternative to CNG storage. It can be argued that low pressure ANG has reached near parity with CNG, since the storage capacity of CNG (2400 psi) is rated at 190 V/V, while low pressure ANG (500 psi) has reached storage capacities of 180 V/V in the laboratory. A program, which extends laboratory results to a full-scale vehicle test, is necessary before ANG technology will receive widespread acceptance. The objective of this program is to field test a 150 V/V ANG vehicle in FY 1994. As a start towards this goal, carbon adsorbents have been screened by Brookhaven for their potential use in a natural gas storage system. This paper reports on one such carbon, trade name Maxsorb, manufactured by Kansai Coke under an Amoco license. DOE

ROTORDYNAMIC AND LEAKAGE CHARACTERISTICS OF A 4-STAGE BRUSH SEAL Final Report, 30 Oct. 1988 - 30 Aug. 1992
K. J. Conner and D. W. Childs Dec. 1992 147 p
(Contract F33615-88-C-2908)
(AD-A266012; WL-TR-92-2125) Avail: CASI HC A07/MF A02

Experimental results are presented for the direct and cross-coupled stiffness and damping coefficients as well as the leakage performance for a 4-stage brush seal. Variable test parameters include the inlet pressure, pressure ratio, shaft speed, fluid prerotation, and seal spacing. Direct

damping is shown to increase with running speed; otherwise, the rotordynamic coefficients are relatively insensitive to changes in the test parameters. Cross-coupled stiffness is generally unchanged by increasing the inlet tangential velocity to the seals, suggesting that the brush seal is not affected by inlet swirl. Direct stiffness is shown to increase with frequency; however, the magnitudes of direct stiffness are always positive. Cross-coupled stiffness increases slightly with frequency; yet not as drastically as direct stiffness. Comparisons of test results for the 4-stage brush seal with an 8-cavity labyrinth showed superior rotordynamics performance for the brush seal; viz., large values for direct stiffness and lower values for the (destabilizing) cross-coupled stiffness coefficient. The damping for brush seals is smaller, but comparable to labyrinth seals. The whirl-frequency ratio is always smaller for the brush seal. DTIC

FORCE REFLECTING HAND CONTROLLER FOR MANIPULATOR TELEOPERATION Final Technical Report, Jul. 1989 - Jul. 1991
Mark D. Bryfogle 31 Dec. 1991 115 p
(Contract NAS7-1069; SBIR-05.01-3600)
(NASA-CR-191345; NAS 1.26:191345) Avail: CASI HC A06/MF A02

A force reflecting hand controller based upon a six degree of freedom fully parallel mechanism, often termed a Stewart Platform, has been designed, constructed, and tested as an integrated system with a slave robot manipulator test bed. A force reflecting hand controller comprises a kinesthetic device capable of transmitting position and orientation commands to a slave robot manipulator while simultaneously representing the environmental interaction forces of the slave manipulator back to the operator through actuators driving the hand controller mechanism. The Stewart Platform was chosen as a novel approach to improve force reflecting teleoperation because of its inherently high ratio of load generation capability to system mass content and the correspondingly high dynamic bandwidth. An additional novelty of the program was to implement closed loop force and torque control about the hand controller mechanism by equipping the handgrip with a six degree of freedom force and torque measuring cell. The mechanical, electrical, computer, and control systems are discussed and system tests are presented. Author (revised)

COMPENDIUM OF EXECUTIVE SUMMARIES FROM THE MAGLEV SYSTEM CONCEPT DEFINITION Final Report, Nov. 1991 - Sep. 1992
Mar. 1993 124 p Sponsored by Federal Railroad Administration, Washington, DC, and Corps. of Engineers, Washington, DC Prepared in cooperation with Foster-Miller, Inc., Waltham, MA, and Gruman Aerospace Corp., Betpage, NY Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-154938/GAR; DOT/FRA/NMI-93/02) Avail: CASI HC A06

The Executive Summaries from the four System Concept Definition (SCD) studies awarded under the National Maglev Initiative are included. These summaries present the technical feasibility, performance, capital, operating, and maintenance costs for a maglev system that would be available by the year 2000. Performance on a hypothetical route, provided to test these concepts in order for the NMI to make performance and cost comparisons, is briefly discussed. This compendium constitutes the principle publication of those SCD reports on technical matters.

FLEX-GEAR ELECTRICAL POWER TRANSMISSION Final Report, 15 Jul. 1992 - 15 Sep. 1993
John Vranish and Jonathan Peritt 15 Sep. 1993 133 p
(Grant NAG5-2004)
(NASA-CR-194422; NAS 1.26:194422) Avail: CASI HC A07/MF A02

This study was conducted to develop an alternative way of transferring electricity across a continuously rotating joint, with little wear and the potential for low electrical noise. The problems with wires, slip rings, electromagnetic couplings, and recently invented roll-rings are discussed. Flex-gears, an improvement of roll-rings, are described. An entire class of flexgear devices is developed. Finally, the preferred flex-gear device is optimized for maximum electrical contact and analyzed for average mechanical power loss and maximum stress. For a device diameter of six inches, the preferred device is predicted to have a total electrical contact area of 0.066 square inches. In the preferred device, a small amount of internal sliding produces a 0.003 inch-pound torque that resists the motion of the device. Author (revised)

TECHNIQUES FOR IMPROVING THE PERFORMANCE OF A SIMPLIFIED ELECTRONIC FUEL CONTROLLER WITH INCREMENTAL ACTUATION FOR SMALL GAS TURBINE ENGINES Ph.D. Thesis
Antanios Ioannou Georgantas Apr. 1990 273 p
(ISBN-0-315-56062-2; CTN-93-60719) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

Concepts are introduced which improve the performance of an inexpensive electronic fuel control unit for small gas turbine engines suitable for use in small aircraft and helicopters. A conventional hydromechanical fuel control unit is modified and adapted for digital electronic control. The conversion involves the replacement of the pneumatic computing and actuating mechanism with digital computation and incremental electronic actuation of a flow metering valve. A mathematical model of the unit is developed, implemented, and validated. The model is used for simulation and study of the system dynamics. Some new methods are applied in the design and development of a digital controller. An optimization scheme for tuning the controller is formulated and implemented experimentally. As a next step toward improvement of the simple electronic fuel controller, a concept of two electronic actuators, one operating the metering valve and the other a bypass valve, is introduced and investigated. Higher flexibility and faster transient response, as compared to the conventional system and the single actuator unit, are demonstrated. The possibility of a backup scheme in case of failure of one of two actuating mechanisms is also discussed. Author (CISTI)

GENERALIZED IMPEDANCE CONTROL OF A REDUNDANT MANIPULATOR Ph.D. Thesis
Michael Peter Hennessey 1993 242 p
Avail: Univ. Microfilms Order No. DA9312488

In this thesis, we consider the general problem of impedance control of an n degree-of-freedom (dof) serial link manipulator with emphasis on the redundant manipulator case. Other approaches in the literature insist upon keeping the number of impedance dofs less than or equal to the number of manipulator dofs with a clear partitioning of se lf motion and desired end effect or motion. Our approach does not possess these limitations and is based on, and even encourages, the imposition of multiple conflicting impedance objectives (including distributed impedances). These desired impedances can be either 'fictitious' or actual, 'link' or 'joint' based, and can be customized to a particular application of interest. Impedance interpolation is the key vehicle for resolving the multiple (and likely conflicting) impedance objectives to produce a blended or compromise solution. We show (using singular value decomposition) that provided that a sufficient number (or distribution) and type of impedance dofs are specified (e.g. is greater than or equal to n for the discrete case), a stable control law solution will always exist. Furthermore, singularity robustness of the control law solution can be increased by judiciously adding impedance dofs to the problem. The resultant local dynamics are studied and shown to be conditionally stable and can always be made unconditionally stable by introducing sufficiently high joint impedances. Experimental aspects of

Generalized Impedance Control are studied for the case of interpolated stiffness control of a 3 dof serial link manipulator. In addition, a computationally efficient approach to solving the inverse kinematics problem for an n degree-of-freedom (dof) serial link manipulator is presented; regardless of the manipulator's kinematic configuration or whether it is redundant or nonredundant. The method referred to as the 'multiplexed joint' method is based on individually moving joints in such a manner as to minimize the weighted norm of the resultant linearized location error transformation. A higher level joint scheduling algorithm controls which joints are to be moved. The simplest form of this joint scheduling algorithm would be to cyclicly sequence through all of the joints--hence the analogy to the multiplex or operation. Simulation results are presented for the case of a 3 dof planar redundant manipulator. Author

DYNAMICS AND DESIGN OF NONHOLONOMIC ROBOTIC MECHANICAL SYSTEMS Ph.D. Thesis
Subir Kumar Saha 1991 202 p
(ISBN-0-315-72009-3) Avail: Univ. Microfilms Order No. DANN72009

An approach in formulating kinematic constraints and a methodology for the dynamic modeling of mechanical systems with nonholonomic couplings are presented. The method presented is based on the natural orthogonal complement (NOC) of the kinematic constraint matrix associated with the linear homogeneous form of the kinematic constraints. The method of the NOC is used to model mechanical systems consisting of multiple-loop kinematic chains with nonholonomic constraints. Moreover, the method of the NOC, when coupled with an optimization technique, can be used for the feedforward control of redundantly actuated systems, as shown. The method of the NOC is first discussed in detail with the aid of an example of a two-wheeled mechanical system. Then, nonholonomic robotic mechanical systems, for example, automatic guided vehicles (AGV's), are analyzed for simulation purposes. As a result, general purpose software is developed for the kinematic and dynamic analyses of three-degree-of-freedom (3-DOF) AGV's. These AGV's use omnidirectional wheels which, in contrast to conventional wheels, e.g., the wheels in an automobile, result in 3-DOF motion of the vehicle. Isotropic designs of 3-DOF AGV's for direct kinematics are proposed, which should enhance the control of the vehicle. With advanced computer graphics, a common trend is to use motion animation in assessing the time response of the systems under study. This brought about issues of algorithmic complexity that are inherent to motion animation. These issues are addressed with an example involving the attitude representation of a rigid body and the choice of a suitable coordinate frame in representing the dynamic equations of motion. ROBUST SYNTHESIS OF DISCRETE-TIME MULTIVARIABLE CONTROL SYSTEMS WITH INDUCED DELAYS Ph.D. Thesis
Hong Shen 1992 142 p
Avail: Univ. Microfilms Order No. DA9311722

In many real-time distributed control systems such as those for advanced aircraft, spacecraft, and autonomous manufacturing plants, the sensor and control signals within a feedback loop are subjected to delays induced by multiplexed data communication networks. From this perspective, algorithms for synthesizing multivariable discrete-time control systems with induced delays were formulated by stochastic and deterministic approaches. In the stochastic approach, a linear quadratic stochastic regulator was proposed to account for the randomly varying distributed delays in the closed loop system, which was then improved by a stochastic estimator for output feedback control. In the deterministic approach, a multi-step delay compensator was proposed, assuming that the sensor, controller, and actuator have a constant and identical sampling period T, and the randomly varying delays in the closed loop system are bounded. Focus is on improvement of performance and stability robustness of the multi-step delay compensator. The specifications for performance and stability robustness are expressed as matrix-valued functions of frequency. Three algorithms are proposed to minimize the H2-norm of the sensitivity error matrix. The third algorithm, which is an extension of the standard loop transfer recovery (LTR) procedure from one-step prediction to the general case of the p-step prediction (p is greater than or equal to 1), is found to be most suitable among the proposed three algorithms from the perspectives of performance, stability robustness, and computational simplicity. It is shown that the concept of the steady-state minimum-variance filter gain as the H2-minimal solution of the difference between the target sensitivity matrix and the actual sensitivity matrix for one-step prediction does hold for p-step prediction (p is greater than 1). Therefore, the proposed multi-step delay compensator can be used with the synthesized observer gain and adjusted controller gain to mitigate the detrimental effects of the induced delays, and maintain the performance and stability robustness of the closed loop control system. The efficacy of the control synthesis procedure for delay compensation is demonstrated via simulation experiments using the flight dynamic model of an advanced aircraft. Dissert. Abstr.

THE EFFECT OF TIN COATINGS ON THE ROLLING CONTACT FATIQUE BEHAVIOR OF M50 BEARING STEEL Final Report
R. M. Middleton, P. J. Huang, M. G. H. Wells, and R. A. Kant (Naval Research Lab., Washington, DC.) Dec. 1992 44 p
(ARL-TR-40) Avail: CASI HC A03/MF A01

There is a continuing requirement for improved bearing performance for both commercial and military applications. Service temperatures are increasing steadily due to increased power requirements and corrosion of components remains a major concern as well, particularly for bearings in military systems. A number of different coatings were applied to VIM-VAR M50 bearing steel to improve both corrosion resistance and rolling contact fatigue behavior. This report deals specifically with coatings produced by the ion beam assisted deposition (IBAD) of TiN, details of the coating process, and test results obtained. The rolling contact fatigue performance of IBAD TiN coated M50 samples demonstrated increased lifetime performance and durability for a 1 micrometer thick coating. Preliminary data on corrosion properties is also presented. Author (revised)

EVALUATION OF THE SHUTTLE REMOTE MANIPULATOR Final Report
Louis J. Everett and R. C. Redfield 23 Sep. 1993 17 p
(Grant NAG9-450)
(NASA-CR-194351; NAS 1.26:194351) Avail: CASI HC A03/MF A01

The objective initially proposed was to analyze shuttle remote manipulator (SRM) performance data collected during a Shuttle Flight. The data was to consist of video TRAC data collected via a video recorder. Unfortunately, the flight never collected the data due to higher priority experiments superseding it. As a result, the research team at Texas A&M was directed to work on several other pressing issues regarding the TRAC sensor. All but one of these issues were reported earlier in the form of periodic status reports. In fulfillment of the grant conditions, the last issue investigated is being reported as the final report. Ordinarily, a TRAC sensor determines the orientation of an object by analyzing the image reflected from a mirror target. The concern addressed is to develop a method for using the TRAC sensor when the target does not reflect a usable image. Author (revised)

PISTON ENGINE INTAKE AND EXHAUST SYSTEM DESIGN

P. O. A. L. Davies Jul. 1993 58 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ISVR-TR-222) Copyright Avail: Issuing Activity

The aim of intake and exhaust system design is to control the transfer of acoustic energy from the sources and its emission by the system with minimal loss of engine performance. A rational design process depends on the adoption of a design methodology based on predictive modeling of acoustic behavior. Virtually any system geometry can be modeled by breaking it down to a sequence of simple elements or chambers. An initial design layout is then produced with simple parametric models of individual element behavior. This design is then refined to prototype level by systematic modification of detail using realistic assessments of system performance in its operational environment. Following prototype validation by practical testing, further necessary development is again assisted by predictive modeling. The application of appropriate procedures is illustrated by a series of practical examples. These concern improvements in interior noise by control of intake noise, of vehicle performance by reducing flow losses, of the environment by control of exhaust emissions, and lastly with the control of flow noise. The report concludes with a brief outline of current and new developments involving integrated design procedures.

SOME ASPECTS OF SHEET FORMING SIMULATION USING EXPLICIT FINITE ELEMENT TECHNIQUES

R. G. Whirley, B. E. Engelmann, and R. W. Logan 28 Jul. 1992 9 p Presented at the Winter Annual Meeting of the ASME, Anaheim, CA, 8-13 Nov. 1992

(Contract W-7405-eng-48)

(DE93-012479; UCRL-JC-111227; CONF-921110-49) Avail: CASI HC A02/MF A01

This paper discusses some aspects of the application of the explicit nonlinear finite element code DYNA3D to the numerical simulation of sheet forming processes. Although DYNA3D is intrinsically a code for transient dynamic response, it has been successfully applied to the quasistatic sheet forming problem by slow application of the loads. Although somewhat nontraditional, this approach has proven very robust in application to large-scale problems. This paper discusses the components of a successful sheet forming analysis, including constitutive modeling, contact definition, guidelines for load application, and some suggestions for solution evaluation. Further, this paper illustrates the use of DYNA3D to compute the Limiting Draw Ratio as a function of material anisotropy and compares the computed results for 3-D forming problems with experimental data. COMPATIBILITY TESTING OF VACUUM SEAL MATERIALS

P. A. Foster and W. A. Rodin May 1993 30 p

(Contract DE-AC04-91AL-65030)

(DE93-014366; MHSMP-93-08) Avail: CASI HC A03/MF A01

Small scale materials compatibility testing was conducted for three elastomers considered for use as vacuum seal materials: Adiprene MOCA-cured; Adiprene Cyanacured; and Sylgard silastic rubber. The tests were conducted using orthogonal array designed experiments for each of the elastomers placed in contact with three materials commonly used during weapon disassembly operations: Duxseal, Sylgard 186 grease, and 2-propyl alcohol. The test results indicated that only the 2-propyl alcohol had a significant effect on the elastomer hardness and physical properties. The alcohol had the largest effect on the two Adiprene materials, and the silastic rubber was the least affected. DOE

DESIGN AND APPLICATION OF ELECTROMECHANICAL ACTUATORS FOR DEEP SPACE MISSIONS Annual Report, 16 Aug. 1992 - 15 Aug. 1993

Tim A. Haskew and John Wander Sep. 1993 72 p

(Grant NAG8-240)

(NASA-CR-194145; NAS 1.26:194145; BER-597-163) Avail: CASI HC A04/MF A01

The annual report Design and Application of Electromechanical Actuators for Deep Space Missions is presented. The reporting period is 16 Aug. 1992 to 15 Aug. 1993. However, the primary focus will be work performed since submission of our semi-annual progress report in Feb. 1993. Substantial progress was made. We currently feel confident in providing guidelines for motor and control strategy selection in electromechanical actuators to be used in thrust vector control (TVC) applications. A small portion was presented in the semi-annual report. At this point, we have implemented highly detailed simulations of various motor/drive systems. The primary motor candidates were the brushless dc machine, permanent magnet synchronous machine, and the induction machine. The primary control implementations were pulse width modulation and hysteresis current control. Each of the two control strategies were applied to each of the three motor choices. With either pulse width modulation or hysteresis current control, the induction machine was always vector controlled. A standard test position command sequence for system performance evaluation is defined. Currently, we are gathering all of the necessary data for formal presentation of the results. Briefly stated for TVC application, we feel that the brushless dc machine operating under PWM current control is the best option. Substantial details on the topic, with supporting simulation results, will be provided later, in the form of a technical paper prepared for submission and also in the next progress report with more detail than allowed for paper publication. MACHINERY DYNAMICS ACTIVITIES IN CANADIAN INDUSTRIES

Robert J. Rogers and Paul Y. Kim (National Research Council of Canada, Vancouver, British Columbia.) May 1992 39 p

(IME-MET-TR-006; CTN-93-60781) Avail: CASI HC A03/MF A01

Results are presented from a survey of Canadian industries to determine their activities related to machinery dynamics. Responses were obtained from industries in the categories of electric utilities, consultants, petrochemicals, research laboratories, aircraft related, and machinery manufacturers. The permanent manpower allocated for tasks such as monitoring machinery vibration, balancing, fault diagnosis, or rotor dynamic analysis has increased significantly in the past five years. A list of individuals who can be contacted to exchange information is included. The use of various instruments is also documented. Small computers and microprocessor based instruments are widely used to record and process vibration data. A wide variety of standards and guides are used for allowable vibration severity and residual imbalance. Some data were obtained for typical normal, alarm, and shutdown vibration values for twenty categories of equipment. The median cost of setting up a vibration program was generally one percent of the total cost of plant and machinery. Fifteen research projects in machinery dynamics are tabulated. Author (CISTI)

COMPUTER PROGRAM FOR ANALYSIS OF HIGH SPEED, SINGLE ROW, ANGULAR CONTACT, SPHERICAL ROLLER BEARING, SASHBEAN. VOLUME 1: USER'S GUIDE Final Report

Arun K. Aggarwal Sep. 1993 68 p Prepared for Sikorsky Aircraft, Stratford, CT

(Contract NAS3-25423; RTOP 505-63-36; DA Proj. 1L1-62211-A-47-A)
(NASA-CR-191183; E-8089-Vol-1; NAS 1.26:191183; ARL-CR-82-Vol-1)
Avail: CASI HC A04/MF A01

The computer program SASHBEAN (Sikorsky Aircraft Spherical Roller High Speed Bearing Analysis) analyzes and predicts the operating characteristics of a Single Row, Angular Contact, Spherical Roller Bearing (SRACSRB). The program runs on an IBM or IBM compatible personal computer, and for a given set of input data analyzes the bearing design for it's ring deflections (axial and radial), roller deflections, contact areas and stresses, induced axial thrust, rolling element and cage rotation speeds, lubrication parameters, fatigue lives, and amount of heat generated in the bearing. The dynamic loading of rollers due to centrifugal forces and gyroscopic moments, which becomes quite significant at high speeds, is fully considered in this analysis. For a known application and it's parameters, the program is also capable of performing steady-state and time-transient thermal analyses of the bearing system. The steady-state analysis capability allows the user to estimate the expected steady-state temperature map in and around the bearing under normal operating conditions. On the other hand, the transient analysis feature provides the user a means to simulate the 'lost lubricant' condition and predict a time-temperature history of various critical points in the system. The bearing's 'time-to-failure' estimate may also be made from this (transient) analysis by considering the bearing as failed when a certain temperature limit is reached in the bearing components. The program is fully interactive and allows the user to get started and access most of its features with a minimal of training. For the most part, the program is menu driven, and adequate help messages were provided to guide a new user through various menu options and data input screens. All input data, both for mechanical and thermal analyses, are read through graphical input screens, thereby eliminating any need of a separate text editor/word processor to edit/create data files. Provision is also available to select and view the contents of output files on the monitor screen if no paper printouts are required. A separate volume (Volume-2) of this documentation describes, in detail, the underlying mathematical formulations, assumptions, and solution algorithms of this program. Author (revised)

Avail: CASI HC A03/MF A01

Spherical roller bearings have typically been used in applications with speeds limited to about 5000 rpm and loads limited for operation at less than about 0.25 million DN. However, spherical roller bearings are now being designed for high load and high speed applications including aerospace applications. A computer program, SASHBEAN, was developed to provide an analytical tool to design, analyze, and predict the performance of high speed, single row, angular contact (including zero contact angle), spherical roller bearings. The material presented is the mathematical formulation and analytical methods used to develop computer program SASHBEAN. For a given set of operating conditions, the program calculates the bearings ring deflections (axial and radial), roller deflections, contact areas stresses, depth and magnitude of maximum shear stresses, axial thrust, rolling element and cage rotational speeds, lubrication parameters, fatigue lives, and rates of heat generation. Centrifugal forces and gyroscopic moments are fully considered. The program is also capable of performing steady-state and time-transient thermal analyses of the bearing system. Author (revised)

MACHINING AND GRINDING: HIGH RATE DEFORMATION IN PRACTICE
P. S. Follansbee 1993 5 p Presented at the 1993 ASPE Spring Topical Meeting, Tucson, AZ, 13-15 Apr. 1993
(Contract W-7405-eng-36)
(DE93-010718; LA-UR-93-791; CONF-9304106-1) Avail: CASI HC A01/MF A01

Machining and grinding are well-established material-working operations involving highly non-uniform deformation and failure processes. A typical machining operation is characterized by uncertain boundary conditions (e.g., surface interactions), three-dimensional stress states, large strains, high strain rates, non-uniform temperatures, highly localized deformations, and failure by both nominally ductile and brittle mechanisms. While machining and grinding are thought to be dominated by empiricism, even a cursory inspection leads one to the conclusion that this results more from necessity arising out of the complicated and highly interdisciplinary nature of the processes than from the lack thereof. With these conditions in mind, the purpose of this paper is to outline the current understanding of strain rate effects in metals. DOE

A test fixture for measuring the dynamic performance of candidate high-temperature engine seal concepts was installed at NASA Lewis Research Center. The test fixture was designed to evaluate seal concepts under development for advanced hypersonic engines, such as those being considered for the National Aerospace Plane (NASP). The fixture can measure dynamic seal leakage performance from room temperature up to 840 C (1550 F) and air pressure differentials up to 690 kPa (100 psi). Performance of the seals can be measured while sealing against flat or distorted walls. In the fixture two seals are preloaded against the sides of a 30 cm (1 ft) long saber that slides transverse to the axis of the seals, simulating the scrubbing motion anticipated in these engines. The capabilities of this test fixture along with preliminary data showing the dependence of seal leakage performance on high temperature cycling are addressed. Author (revised)

The research has been concerned with a comprehensive analysis of robotic end effectors including frictional energy dissipation and rigid-body as well as flexible elements. The design analysis involves a set of nonlinear simultaneous equations for quantifying such phenomena as preloads, internal forces, frictional drag, kinematic and dynamic performance and optimization criteria, energy losses and efficiency. The analysis facilitates the optimization of robotic systems in the design stage. A new concept, which we may call a cylindrical actuator, was developed in the course of the research (and communicated to the U.S. Army Research Office (ARO)) and may have significant applications, both in robotics, as well as in other areas of mechanical design. VISART: ARTIFICIAL VISION FOR INDUSTRIAL USE. A COMPREHENSIVE SYSTEM Ph.D. Thesis [VISART - VISAO ARTIFICIAL PARA USO INDUSTRIAL: UM SISTEMA ABRANGENTE]
Sdnei deBritoAlves Feb. 1992 185 p In PORTUGESE
(INPE-5379-TDI/474) Avail: CASI HC A09/MF A02

A thorough description of a Computer Vision System applied to inspection activities is presented, all of the life-cycle stages of this system being dealt with in detail. It was conceived, designed, and implemented within the scope of an applied research, entitled (VISART) Artificial Vision for Industrial Use: A Comprehensive System. During the effort employed in the development of this work, significant contributions were incorporated to the state-of-the-art in processing of binary images. The VISART system includes resources, concepts, and inovations not yet seen in similar systems. A new terminology with technical terms nearer to those used by engineers and technicians, in industrial environments, is proposed and it might contribute for acceptance and dissemination of Vision Systems in these environments. Concepts of Group Technology have been associated to Vision Systems and they might contribute for a greater integration of the industrial process automation. A special data structure was conceived for image data storage, allowing to reduce the processing time of algorithms of industrial part features-extraction. A library with a considerable number of feature extraction algorithms, used for recognition, acceptance or rejection of industrial products under inspection, was conceived and implemented. New algorithms can be appended to this library by the user, without the necessity of reprogramming the modules of the VISART system. Within this respect lies one of the main comprisement features of VISART. It has a graphic editor which makes possible to use it in activities such as teaching and formation of skilled personnel in the area of vision. At first, this facility exempts the use of sensors, making it more economic for use in these activities. All in all, this research work is a pioneer in Brazil, and its divulgation must contribute significantly for the dissemination and growth of the computer vision area applied to inspection, in the country. AUTOMATED CRACK IDENTIFICATION FOR CEMENT PASTE Final Report, 4 Jun. 1990 - 13 Apr. 1993
Kirk W. Ketcham, Francisco A. Romero, David Darwin, Shanglong Gong, and Mohamed N. Abou-Zeid Apr. 1993 77 p
(Grant AF-AFOSR-0296-89)
(AD-A265753; SM-34; AFOSR-93-0385TR) Avail: CASI HC A05/MF A01

The development of an automated procedure for the identification of microcracks in cementitious materials is described. The degree and nature of microcracking is measured using backscattered electron images obtained with an integrated scanning electron microscope/image analysis system. Multiple images for specimens are analyzed using a computer program developed to identify and measure microcracks within the individual phases of cement paste. The procedure is developed to assist in the determination of the roles played by individual phases in cement paste in the formation and propagation of microcracks. Procedures for specimen testing, preparation, imaging, and crack analysis are described, along with a description of the development of the analysis program. The analysis capabilities of the program are demonstrated. The gray level of epoxy-filled cracks in polished cement paste specimens is affected by the atomic number density of underlying and adjacent phases. As a result, cracks cannot be identified based on gray level alone. Epoxy-filled cracks in polished cement paste specimens can be identified of geometric requirements; combined procedures that establish the floor of a crack, minimum gradient and gray level adjacent to cracks, and minimum differences in gray level between the floor of a crack and adjacent solid phases provide a reproducible and consistent technique for crack identification in cement paste. QUANTITATIVE MAPPING OF PORE FRACTION VARIATIONS IN SILICON NITRIDE USING AN ULTRASONIC CONTACT SCAN TECHNIQUE
Don J. Roth, James D. Kiser, Suzanne M. Swickard, Steven A. Szatmary (Cleveland State Univ., OH.), and David P. Kerwin (Cleveland State Univ., OH.) Washington Aug. 1993 36 p
(RTOP 506-43-11)
(NASA-TP-3377; E-7558; NAS 1.60:3377) Avail: CASI HC A03/MF A01

An ultrasonic scan procedure using the pulse-echo contact configuration was employed to obtain maps of pore fraction variations in sintered silicon nitride samples in terms of ultrasonic material properties. Ultrasonic velocity, attenuation coefficient, and reflection coefficient images were obtained simultaneously over a broad band of frequencies (e.g., 30 to 110 MHz) by using spectroscopic analysis. Liquid and membrane (dry) coupling techniques and longitudinal and shear-wave energies were used. The major results include the following: Ultrasonic velocity (longitudinal and shear wave) images revealed and correlated with the extent of average through-thickness pore fraction variations in the silicon nitride disks. Attenuation coefficient images revealed pore fraction nonuniformity due to the scattering that occurred at boundaries between regions of high and low pore fraction. Velocity and attenuation coefficient images were each nearly identical for machined and polished disks, making the method readily applicable to machined materials. Velocity images were similar for wet and membrane coupling. Maps of apparent Poisson's ratio constructed from longitudinal and shear-wave velocities quantified Poisson's ratio variations across a silicon nitride disk. Thermal wave images of a disk indicated transient thermal behavior variations that correlated with observed variations in pore fraction and velocity and attenuation coefficients. Author

The study by the American Productivity & Quality Center (APQC) was commissioned by Loral Space Information Systems, Inc. and the National Aeronautics and Space Administration (NASA) to evaluate internal assessment systems. APQC benchmarked approaches to the internal assessment of quality management systems in three phases. The first phase included work conducted for the International Benchmarking Clearinghouse (IBC) and consisted of an in-depth analysis of the 1991 Malcolm Baldrige National Quality Award criteria. The second phase was also performed for the IBC and compared the 1991 award criteria among the following quality awards: Deming Prize, Malcolm Baldrige National Quality Award, The President's Award for Quality and Productivity Improvement, The NASA Excellence Award (The George M. Lowe Trophy) for Quality and Productivity Improvement and the Shigeo Shingo Award for Excellence in Manufacturing. The third phase compared the internal implementation approaches of 23 companies selected from American industry for their recognized, formal assessment systems. Derived from text

Avail: CASI HC A02/MF A03

This paper presents two different approaches to performing self-assessments of continuous improvement activities. Case Study 1 describes the activities performed by JSC to assess the implementation of continuous improvement efforts at the NASA Center. The JSC approach included surveys administered to randomly selected NASA personnel and personal interviews with NASA and contractor management personnel. Case Study 2 describes the continuous improvement survey performed by the JSC Safety, Reliability, and Quality Assurance (SR&QA) organization. This survey consisted of a short questionnaire (50 questions) administered to all NASA and contractor SR&QA personnel. The questionnaire is based on the eight categories of the President's Award for Quality and Productivity Improvement. It is designed to objectively determine placement on the TQ benchmark and identify a roadmap for improvement. Derived from text

WHAT'S THE BOTTOM LINE PAYBACK FOR TQM?
Brian Usilaner *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence; The Journey Continues. Conference Presentations 1992 17 p (For primary document see N94-13153 02-38)
Avail: CASI HC A03/MF A03

The purpose of this article is to explore in detail TQM's impact on improving organization performance and how effective TQM strategies are designed and implemented. Both of these issues are addressed primarily by a discussion of a recent study of TQM efforts conducted by the U.S. General Accounting Office (GAO). The GAO study examines the impact of formal TQM improvement strategies on the performance of selected U.S. companies. The study grew out of a concern by a number of U.S. Congressmen that little is known about the impact of various quality-related efforts many companies have adopted to remain viable and profitable in an increasingly competitive world marketplace. Specifically, the study addresses: what has been the performance impact of adopting TQM improvement strategies, how has improved quality been achieved, and what lessons may be applicable to U.S. companies in general. A number of other studies are also used to expand upon the GAO data.

PARTNERSHIP WITH THE CUSTOMER
Gregory S. Trachta *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence: The Journey Continues. Conference Presentations 1992 8 p (For primary document see N94-13153 02-38)
Avail: CASI HC A02/MF A03

This discussion will recount some historical observations about establishing partnerships with the customer. It suggests that such partnerships are established as the natural evolutionary product of a continuous improvement culture. Those are warm, ethereal terms about a topic that some people think already suffers from an excess of hot air. We will focus on some real-world activities and workplace artifacts to show there are substantive concepts behind the TQM buzzwords.

STRATEGIC PLANNING AS A FOCUS FOR CONTINUOUS IMPROVEMENT. A CASE STUDY
John W. ONeill and Lyn Gordon-Winkler *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence: The Journey Continues. Conference Presentations 1992 12 p (For primary document see N94-13153 02-38)
Avail: CASI HC A03/MF A03

What do most of the successful people and organizations in our world have in common? Instead of worrying about the future, they work to create it. They have a plan, or a vision of what they want to accomplish and they focus their efforts on success. Strategic planning has been described as a disciplined, ongoing process to produce fundamental decisions and actions that shape what an organization is, what it does, and how it will respond to a changing environment. This case study discussion will evaluate the relationship between strategic planning and Total Quality Management (TQM), or continuous improvement, through the experience of the NASA Johnson Space Center in developing a strategy for the future. That experience clearly illustrates the value of strategic planning in setting the framework and establishing the overall thrust of continuous improvement initiatives. Equally significant, the fundamentals of a quality culture such as strong customer and supplier partnerships, participative involvement, open communications, and ownership were essential in overcoming the challenges inherent in the planning process. A reinforced management commitment to the quality culture was a clear, long-term benefit. Derived from text

THE POWER OF CROSS-FUNCTIONAL TEAMS IN DRIVING TOTAL QUALITY
Tim M. McClung and Tom J. McMaster *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence: The Journey Continues. Conference Presentations 1992 21 p (For primary document see N94-13153 02-38)
Avail: CASI HC A03/MF A03

Garrett Canada, a Division of Allied-Signal Aerospace Canada, has

been a member of the Canadian aerospace industry for 40 years. Although Garrett Canada has always been a profitable division with a solid market share, the changing and turbulent business environment and globalization of the aerospace industry has created new demands and challenges. The marketplace is demanding faster introduction of new products, as well as shorter leadtimes for repairs and spares. It was recognized that reducing cycle times for new products and for ongoing production would not only satisfy our customers, it would also enhance our business performance through reduced inventories, lower past due, and more responsiveness to change. It was evident that drastic function changes were required if we were to maintain our position as a premier aerospace supplier. The challenge was to convert a stable, somewhat slow-paced work environment with strong functional boundaries into a boundaryless world class team functioning in a total quality environment and focused on customer satisfaction. Complete and uncompromised customer satisfaction has become our driving force, with Total Quality being our engine to continuously improve our processes and increase our speed. The way in which this transition has been brought about is the subject of this presentation. Author (revised)

SPACECRAFT COst REduction TEAM (SCORE): TQM/CI ON A MASSIVE SCALE

Jerry D. Bullard *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence: The Journey Continues. Conference Presentations 1992 10 p (For primary document see N94-13153 02-38)

Avail: CASI HC A02/MF A03

The business of building satellites and space systems has matured. Few missions require, or can afford, excellent performance at any price. The new paradigm is doing more with less, providing quality systems at lower cost--in other words, doing our job 'Faster-Better-Cheaper.' The TRW Spacecraft COst REduction (SCORE) initiative was launched in 1990 by Daniel S. Goldin, then general manager of TRW's Space & Technology Group. The SCORE mission is to apply continuous improvement (CI) techniques to effect major reductions in the cost (our primary goal) and span time (as a corollary) required for the production of spacecraft. SCORE is a multi-year initiative that is having a profound effect on both the procedural and the cultural aspects of how we do business. The objectives of this initiative are being realized. The focus of this paper is not on the results of SCORE per se, but rather on the things we have leaned about how to do continuous improvement on a massive scale, with multilevel (hierarchical) CI teams. The following sections summarize the chronology of the SCORE initiative, from team formation to development of the year-end report for 1991. Lessons learned, the core of this presentation, are discussed--with particular focus on the unique aspects of SCORE. The SCORE initiative is continuing and, as a part of our evolving culture, will never end. It has resulted in profound insights into the way we do work and (the topic at hand) how to do CI for large and complex multidisciplinary development activities. Author (revised)

OBJECT-ORIENTED PRODUCTIVITY METRICS

John L. Connell and Nancy Eller *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence: The Journey Continues. Conference Presentations 1992 8 p (For primary document see N94-13153 02-38)

Avail: CASI HC A02/MF A03

Software productivity metrics are useful for sizing and costing proposed software and for measuring development productivity. Estimating and measuring source lines of code (SLOC) has proven to be a bad idea because it encourages writing more lines of code and using lower level languages. Function Point Analysis is an improved software metric system, but it is not compatible with newer rapid prototyping and object-oriented approaches to software development. A process is presented here for counting object-oriented effort points, based on a preliminary object-oriented analysis. It is proposed that this approach is compatible with object-oriented analysis, design, programming, and rapid prototyping. Statistics gathered on actual projects are presented to validate the approach.

KENNEDY SPACE CENTER'S NASA/CONTRACTOR TEAM-CENTERED TOTAL QUALITY MANAGEMENT SEMINAR: RESULTS, METHODS, AND LESSONS LEARNED

Dennis C. Kinlaw and Jeannette Eads (Edgerton, Germeshausen and Grier, Inc., Cocoa Beach, FL.) *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence: The Journey Continues. Conference Presentations 1992 12 p (For primary document see N94-13153 02-38)

Avail: CASI HC A03/MF A03

It is apparent to everyone associated with the Nation's aeronautics and space programs that the challenge of continuous improvement can be reasonably addressed only if NASA and its contractors act together in a fully integrated and cooperative manner that transcends the traditional boundaries of proprietary interest. It is, however, one thing to assent to the need for such integration and cooperation; it is quite another thing to undertake the hard tasks of turning such a need into action. Whatever else total quality management is, it is fundamentally a team-centered and team-driven process of continuous improvement. The introduction of total quality management at KSC, therefore, has given the Center a special opportunity to translate the need for closer integration and cooperation among all its organizations into specific initiatives. One such initiative that NASA and its contractors have undertaken at KSC is a NASA/Contractor team-centered Total Quality Management Seminar. It is this seminar which is the subject of this paper. The specific purposes of this paper are to describe the following: Background, development, and evolution of Kennedy Space Center's Total Quality Management Seminar; Special characteristics of the seminar; Content of the seminar; Meaning and utility of a team-centered design for TQM training; Results of the seminar; Use that one KSC contractor, EG&G Florida, Inc. has made of the seminar in its Total Quality Management initiative; and Lessons learned.

The Science and Technology Lab (STL) is tasked with the design, development, and application of the science and engineering services. Formed in the early 1970's STL adhered to many traditional attitudes including barriers to communication, excessive management control, parochial strategies, unclear measures of success, lack of customer focus, underutilization of people, and excessive administrative burdens on scientists and engineers. The challenge for the STL was to maximize customer satisfaction through the effective and efficient application of the notable skills and talents of the STL's workforce. In this way, the Lab would begin its exciting journey toward becoming world class. A discussion of this on-going transformation is presented. Author (revised)

NASA JOHNSON SPACE CENTER: TOTAL QUALITY PARTNERSHIP

Charlie Harlan and Alfred A. Boyd (Loral Space Information Systems, Houston, TX.) *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence: The Journey Continues. Conference Presentations 1992 16 p (For primary document see N94-13153 02-38)

Avail: CASI HC A03/MF A03

The development of and benefits realized from a joint NASA, support contractor continuous improvement process at the Johnson Space Center (JSC) is traced. The joint effort described is the Safety, Reliability, and Quality Assurance Directorate relationship with its three support contractors which began in early 1990. The Continuous Improvement effort started in early 1990 with an initiative to document and simplify numerous engineering change evaluation processes. This effort quickly grew in scope and intensity to include process improvement teams, improvement methodologies, awareness, and training. By early 1991, the support contractor had teams in place and functioning, program goals established and a cultural change effort underway. In mid-l991 it became apparent that a major redirection was needed to counter a growing sense of frustration and dissatisfaction from teams and managers. Sources of frustration were isolated to insufficient joint participation on teams, and to a poorly defined vision. Over the next year, the effort was transformed to a truly joint process. The presentation covers the steps taken to define vision, values, goals, and priorities and to form a joint Steering Committee and joint process improvement teams. The most recent assessment against the President's award criteria is presented as a summary of progress. Small, but important improvement results have already demonstrated the value of the joint effort.

SHARED VISIONS: PARTNERSHIP OF ROCKWELL INTERNATIONAL AND NASA COST EFFECTIVENESS ENHANCEMENTS (CEE) FOR THE SPACE SHUTTLE SYSTEM INTEGRATION PROGRAM

Bohdan I. Bejmuk (Rockwell International Corp., Huntsville, AL.) and Larry Williams *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence: The Journey Continues. Conference Presentations 1992 9 p (For primary document see N94-13153 02-38)

Avail: CASI HC A02/MF A03

As a result of limited resources and tight fiscal constraints over the past several years, the defense and aerospace industries have experienced a downturn in business activity. The impact of fewer contracts being awarded has placed a greater emphasis for effectiveness and efficiency on industry contractors. It is clear that a reallocation of resources is required for America to continue to lead the world in space and technology. The key to technological and economic survival is the transforming of existing programs, such as the Space Shuttle Program, into more cost efficient programs so as to divert the savings to other NASA programs. The partnership between Rockwell International and NASA and their joint improvement efforts that resulted in significant streamlining and cost reduction measures to Rockwell International Space System Division's work on the Space Shuttle System Integration Contract is described. This work was a result of an established Cost Effectiveness Enhancement (CEE) Team formed initially in Fiscal Year 1991, and more recently expanded to a larger scale CEE Initiative in 1992. By working closely with the customer in agreeing to contract content, obtaining management endorsement and commitment, and involving the employees in total quality management (TQM) and continuous improvement 'teams,' the initial annual cost reduction target was exceeded significantly. The CEE Initiative helped reduce the cost of the Shuttle Systems Integration contract while establishing a stronger program based upon customer needs, teamwork, quality enhancements, and cost effectiveness. This was accomplished by systematically analyzing, challenging, and changing the established processes, practices, and systems. This examination, in nature, was work intensive due to the depth and breadth of the activity. The CEE Initiative has provided opportunities to make a difference in the way Rockwell and NASA work together - to update the methods and processes of the organizations. The future success of NASA space programs and Rockwell hinges upon the ability to adopt new, more efficient and effective work processes. Efficiency, proficiency, cost effectiveness, and teamwork are a necessity for economic survival. Continuous improvement initiatives like the CEE are, and will continue to be, vehicles by which the road can be traveled with a vision to the future.

TEAMWORK FOR OVERSIGHT OF PROCESSES AND SYSTEMS (TOPS). IMPLEMENTATION GUIDE FOR TOPS VERSION 2.0, 10 AUGUST 1992

Albert A. Strand and Darryl J. Jackson *In* JPL, Ninth Annual NASA/Contractors Conference on Quality and Productivity. World Class Excellence: The Journey Continues. Conference Presentations 1992 31 p (For primary document see N94-13153 02-38)

Avail: CASI HC A03/MF A03

As the nation redefines priorities to deal with a rapidly changing world order, both government and industry require new approaches for oversight of management systems, particularly for high technology products. Declining defense budgets will lead to significant reductions in government contract management personnel. Concurrently, defense contractors are reducing administrative and overhead staffing to control costs. These combined pressures require bold approaches for the oversight of management systems. In the Spring of 1991, the DPRO and TRW created a Process Action Team (PAT) to jointly prepare a Performance Based Management (PBM) system titled Teamwork for Oversight of Processes and Systems (TOPS). The primary goal is implementation of a performance based management system based on objective data to review critical TRW processes with an emphasis on continuous improvement. The processes are: Finance and Business Systems, Engineering and Manufacturing Systems, Quality Assurance, and Software Systems. The team established a number of goals: delivery of quality products to contractual terms and conditions; ensure that TRW management systems meet government guidance and good business practices; use of objective data to measure critical processes; elimination of wasteful/duplicative reviews and audits; emphasis on teamwork--all efforts must be perceived to add value by both sides and decisions are made by consensus; and synergy and the creation of a strong working trust between TRW and the DPRO. TOPS permits the adjustment of oversight resources when conditions change or when TRW systems performance indicate either an increase or decrease in surveillance is appropriate. Monthly Contractor Performance Assessments (CPA) are derived from a summary of supporting system level and process-level ratings obtained from objective process-level data. Tiered, objective, data-driven metrics are highly successful in achieving a cooperative and effective method of measuring performance. The teamwork-based culture developed by TOPS proved an unequaled success in removing adversarial relationships and creating an atmosphere of continuous improvement in quality processes at TRW. The new working relationship does not decrease the responsibility or authority of the DPRO to ensure contract compliance and it permits both parties to work more effectively to improve total quality and reduce cost. By emphasizing teamwork in developing a stronger approach to efficient management of the defense industrial base TOPS is a singular success. Author (revised)

STRUCTURAL INVESTIGATION OF A DAMAGED GRP/FOAM SANDWICH COMPOSITE USING X RAY COMPUTED TOMOGRAPHY
B. Suendermann, J. R. Davis (Monash Univ., Melbourne, Australia.), P. Lambrineas, P. Wells (Monash Univ., Melbourne, Australia.), K. R. Thomson (Melbourne Univ., Parkville, Australia.), R. L. Woodward, G. T. Egglestone, and K. Challis [1993] 10 p
Avail: CASI HC A02/MF A01

Glass-reinforced plastic (GRP)/foam sandwich construction is a method of obtaining stiff lightweight composite structures. These composites find Naval applications in superstructures and in the hulls of vessels requiring a low magnetic signature. The application of such composites requires that they can be inspected by nondestructive testing (NDT) techniques for flaws in manufacturing or for service induced damage, including internal damage from the passage of explosion induced shocks. An investigation of the degree to which x ray computed tomography (CT) can be used to characterize such features, using a composite which contains a number of artifacts of manufacturing, as well as deliberately induced flaws and shock damage is described. ENHANCED NDE SYSTEMS Final Report
28 Jul. 1993 24 p
(Contract NAS8-39394)
(NASA-CR-192603; NAS 1.26:192603) Avail: CASI HC A03/MF A01

The goal of this contractual effort was to evaluate the Langley narrow-band ultrasonic debond detection method for a factory use configuration. Successful accomplishment requires establishing the robustness of the method, and enhancing it if necessary. It is also desirable to strive for simplicity of implementation, such as attachment to in-place scanning devices planned for nondestructive evaluation (NDE) measurements. The contract was established with three phases for the ultrasonic work: (1) establish the method and robustness of the ultrasonic method; (2) follow up on any questions which arise with respect to the method or its implementation and produce a Phase A design; and (3) fabricate and test the Phase A design. This is a report on Phase 1. Derived from text

COMPUTATIONAL PROBLEMS WITH THE BINOMIAL FAILURE RATE MODEL AND INCOMPLETE COMMON CAUSE FAILURE RELIABILITY DATA
P. H. Kvam 1993 6 p Presented at the Interface Computing Science and Statistics, San Diego, CA, 14-17 Apr. 1993
(Contract W-7405-eng-36)
(DE93-014346; LA-UR-93-1980; CONF-9304154-1) Avail: CASI HC A02/MF A01

In estimating the reliability of a system of components, it is ordinarily assumed that the component lifetimes are independently distributed. This assumption usually alleviates the difficulty of analyzing complex systems, but it is seldom true that the failure of one component in an interactive system has no effect on the lifetimes of the other components. Often, two or more components will fail simultaneously due to a common cause event. Such an incident is called a common cause failure (CCF) and is now recognized as an important contribution to system failure in various applications of reliability. We examine current methods for reliability estimation of system and component lifetimes using estimators derived from the binomial failure rate model. Computational problems require a new approach, like iterative solutions via the EM algorithm. DOE

THE EIGHTH ANNUAL NASA/CONTRACTORS CONFERENCE AND 1991 NATIONAL SYMPOSIUM ON QUALITY AND PRODUCTIVITY: EXTENDING THE BOUNDARIES OF TOTAL QUALITY MANAGEMENT Summary Report
Geoffrey B. Templeton, ed. (National Aeronautics and Space Administration, Washington, DC.), Lynne M. Stewart, ed. (National Aeronautics and Space Administration, Washington, DC.), and William T. Still, ed. Apr. 1992 281 p
(NASA-TM-109276; NAS 1.15:109276) Avail: CASI HC A13/MF A03

The Eighth Annual NASA/Contractors Conference and 1991 National Symposium on Quality and Productivity provided a forum to exchange knowledge and experiences in these areas of continuous improvement. The more than 1,100 attendees from government, industry, academia, community groups, and the international arena had a chance to learn about methods, tools, and strategies for excellence and to discuss continuous improvement strategies, successes, and failures. This event, linked via satellite to concurrent conferences hosted by the NASA Goddard Space Flight Center in Greenbelt, Maryland, and Martin Marietta Astronautics Group in Denver, Colorado, also explored extending the boundaries of Total Quality Management to include partnerships for quality within communities and encouraged examination, evaluation, and change to incorporate the principles of continuous improvement. STRUCTURAL DESIGN/MARGIN ASSESSMENT
R. S. Ryan Washington Sep. 1993 80 p
(NASA-TP-3410; M-730; NAS 1.60:3410) Avail: CASI HC A05/MF A01

Determining structural design inputs and the structural margins following design completion is one of the major activities in space exploration. The end result is a statement of these margins as stability, safety factors on ultimate and yield stresses, fracture limits (fracture control), fatigue lifetime, reuse criteria, operational criteria and procedures, stability factors, deflections, clearance, handling criteria, etc. The process is normally called

a load cycle and is time consuming, very complex, and involves much more than structures. The key to successful structural design is the proper implementation of the process. It depends on many factors: leadership and management of the process, adequate analysis and testing tools, data basing, communications, people skills, and training. This process and the various factors involved are discussed. Author (revised)

ON CURVE VEERING AND FLUTTER OF ROTATING BLADES
Dare Afolabi (Purdue Univ., Indianapolis, IN.) and Oral Mehmed Aug. 1993 22 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106282; ICOMP-93-27; E-8020; NAS 1.15:106282) Avail: CASI HC A03/MF A01

The eigenvalues of rotating blades usually change with rotation speed according to the Stodola-Southwell criterion. Under certain circumstances, the loci of eigenvalues belonging to two distinct modes of vibration approach each other very closely, and it may appear as if the loci cross each other. However, our study indicates that the observable frequency loci of an undamped rotating blade do not cross, but must either repel each other (leading to 'curve veering'), or attract each other (leading to 'frequency coalescence'). Our results are reached by using standard arguments from algebraic geometry--the theory of algebraic curves and catastrophe theory. We conclude that it is important to resolve an apparent crossing of eigenvalue loci into either a frequency coalescence or a curve veering, because frequency coalescence is dangerous since it leads to flutter, whereas curve veering does not precipitate flutter and is, therefore, harmless with respect to elastic stability. MICROMECHANICAL STRENGTH EFFECTS IN SHOCK COMPRESSION OF SOLIDS
J. N. Johnson 1993 5 p Presented at the Joint AIRAPT/APS Meeting, Colorado Springs, CO, 28 Jun. - 3 Jul. 1993
(Contract W-7405-eng-36)
(DE93-014425; LA-UR-93-1670; CONF-9306167-4) Avail: CASI HC A01/MF A01

Time-resolved shock-wave measurements and post-shock recovery have long been used for inferring the underlaying micromechanics controlling high-rate deformation of solids; this requires considerable subjective interpretation. In spite of this, progress has been made in experimentation and theoretical interpretation of the shock-compression/release cycle and some of the results are reviewed here for weak shocks. This cycle involves the elements of the elastic precursor, plastic loading wave, pulse duration, release wave, and post-mortem examination. Those topics are examined with emphasis on the second and fourth elements. The Cu and Ta results show how shock data can be used to determine the transition from deformation mechanism of thermal activation to that of dislocation drag. Release-wave studies indicate that the leading observable release disturbance in fcc metals may not be propagating with the ideal longitudinal elastic-wave speed. DOE

THE 3-D MASSIVELY PARALLEL IMPACT SIMULATIONS USING PCTH
H. E. Fang and A. C. Robinson 1992 6 p Presented at the SCSC 1993 Summer Computer Simulation Conference, Boston, MA, 19-21 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-011593; SAND-92-2845C; CONF-930765-2) Avail: CASI HC A02/MF A01

Simulations of hypervelocity impact problems are performed frequently by government laboratories and contractors for armor/anti-armor applications. These simulations need to deal with shock wave physics phenomena, large material deformation, motion of debris particles, and complex geometries. As a result, memory and processing time requirements are large for detailed, three-dimensional calculations. The large massively parallel supercomputing systems of the future will provide the power necessary to greatly reduce simulation times currently required by shared-memory, vector supercomputers. This paper gives an introduction to PCTH, a next-generation shock wave physics code which is being built at Sandia National Laboratories for massively parallel supercomputers, and demonstrates that massively parallel hydrocodes, such as PCTH, can provide highly-detailed, three-dimensional simulations of armor/anti-armor systems. A BENCHMARK BENDING TEST OF A THICK SPECIMEN, PART 1: EXPERIMENTS Research Report No. 6
J. M. Finney and E. Kowal Jun. 1993 45 p
(ARL-RR-6-Pt-1; AR-008-363) Copyright Avail: Issuing Activity

An experiment has been undertaken to provide benchmark data for validating methods of calculating the plastic behavior of metals. In this experiment a 30 mm square-test-section specimen of 7050-T7451 aluminum alloy has been loaded in four-point bending, and the surface distortions of all four faces have been measured with the aid of a square grid pattern imposed on the surfaces before deformation. This part of the report describes the experimental details and gives the results of the material property tests, thus, providing sufficient information for the prediction of surface displacements. Part II of the report gives the measured displacements with which predictions may be compared. Derived from text

MICROMECHANICAL MODELING OF LAMINATED COMPOSITES WITH INTERFACES AND WOVEN COMPOSITES USING THE BOUNDARY ELEMENT METHOD
Robert K. Goldberg and Dale A. Hopkins Oct. 1993 12 p Proposed for presentation at the Eighth American Society for Composites Technical Conference on Composite Materials, Cleveland, OH, 19-21 Oct. 1993
(RTOP 510-01-50)
(NASA-TM-106280; E-8019; NAS 1.15:106280) Avail: CASI HC A03/MF A01

The boundary element method is utilized to analyze the effects of fiber/matrix interfaces on the micromechanical behavior of laminated composites as well as the elastic behavior of woven composites. Effective composite properties are computed for laminated SiC/RBSN and SiC/Ti-15-3 composites, as well as a woven SiC/SiC composite. The properties calculated using the computerized tool BEST-CMS match the experimental results well. Author

DESIGN AND APPLICATION OF A QUASISTATIC CRUSH TEST FIXTURE FOR INVESTIGATING SCALE EFFECTS IN ENERGY ABSORBING COMPOSITE PLATES M.S. Thesis
J. Andre Lavoie and John Morton Washington Jul. 1993 65 p
(Grant NAG1-343; RTOP 505-63-50-09)
(NASA-CR-4526; NAS 1.26:4526) Avail: CASI HC A04/MF A01

A crush test fixture for measuring energy absorption of flat plate specimens from an earlier study was redesigned to eliminate the problem of binding of the load transfer platen with the guide posts. Further modifications were to increase the stroke, and combine the two scaled text fixtures into one. This new crush text fixture was shown to produce

load-displacement histories exhibiting well developed sustained crushing loads over long strokes. An experimental study was conducted on two material systems: AS4/3502 graphite/epoxy, and a hybrid AS4-Kevlar/3502 composite. The effect of geometric scaling of specimen size, the effect of ply level and sublaminate-level scaling of the stacking sequence of the full scale specimens, and the effect of trigger mechanism on the energy absorption capability were investigated. The new crush test fixture and flat plate specimens produced peak and sustained crushing loads that were lower than obtained with the old crush text fixture. The trigger mechanism used influenced the specific sustained crushing stress (SSCS). The results indicated that to avoid any reduction in the SSCS when scaling from the 1/2 scale to full scale specimen size, the sublaminate-level scaling approach should be used, in agreement with experiments on tubes. The use of Kevlar in place of the graphite 45 deg plies was not as effective a means for supporting and containing the 0 deg graphite plies for rushing of flat plates and resulted in a drop in the SSCS. This result did not correlate with that obtained for tubes. Author (revised)

METHODS FOR EVALUATING THE PREDICTIVE ACCURACY OF STRUCTURAL DYNAMIC MODELS Final Report, Jul. 1989 - Dec. 1991
Timothy K. Hasselman and Jon D. Chrostowski Dec. 1991 306 p
(Contract NAS7-1064; SBIR-04.10-2551)
(NASA-CR-191337; NAS 1.26:191337; EMA-TR-91-1152) Avail: CASI HC A14/MF A03

Modeling uncertainty is defined in terms of the difference between predicted and measured eigenvalues and eigenvectors. Data compiled from 22 sets of analysis/test results was used to create statistical databases for large truss-type space structures and both pretest and posttest models of conventional satellite-type space structures. Modeling uncertainty is propagated through the model to produce intervals of uncertainty on frequency response functions, both amplitude and phase. This methodology was used successfully to evaluate the predictive accuracy of several structures, including the NASA CSI Evolutionary Structure tested at Langley Research Center. Test measurements for this structure were within + one-sigma intervals of predicted accuracy for the most part, demonstrating the validity of the methodology and computer code. Author (revised)

A PROBABILISTIC METHOD FOR THE BUCKLING ASSESSMENT OF STIFFENED COMPOSITE SHELLS
Michael C. Shiao (Sverdrup Technology, Inc., Brook Park, OH.), Galib H. Abumeri (Sverdrup Technology, Inc., Brook Park, OH.), Surendra N. Singhal (Sverdrup Technology, Inc., Brook Park, OH.), and Christos C. Chamis Jul. 1993 16 p Presented at the Ninth International Conference on Composite Materials, Madrid, Spain, 12-16 Jul. 1993
(RTOP 510-02-12)
(NASA-TM-106286; E-8024; NAS 1.15:106286) Avail: CASI HC A03/MF A01

A method is described to computationally simulate probabilistic buckling behavior of multilayered composite shells. The simulation accounts for all naturally-occurring uncertainties including those in constituent (fiber/matrix) material properties, fabrication variables, and structure geometry. The method is demonstrated for probabilistically assessing the buckling survivability of a specific case of a stiffened composite cylindrical shell with and without cutouts. The sensitivities of various uncertain variables on the buckling survivability are evaluated at specified reliability. The results show that the buckling survivability for a shell without cutouts depends primarily on shell skin related uncertainties. However, stringer related uncertainties become important for a shell with cutouts. Author (revised)

RESIDUAL CONTACT RESTRAINTS IN CRYOGENICS [CONTRAINTES RESIDUELLES DE CONTACT EN AMBIANCE CRYOTECHNIQUE]
J. F. Cretegny and J. M. deMonicault 1992 22 p In FRENCH Presented at Colloque Contraintes Residuelles, Luso-Bucaco, Portugal, 28-30 Apr. 1992
(ETN-93-94375) Avail: CASI HC A03/MF A01

The use of residual stress measurements to evaluate the state of cryogenic turbomachines, whose surfaces are worn by the working conductions in dry contact, is addressed. Their contribution to the understanding of the reasons of possible ruptures is considered. It is stated that residual stress measurements should be used as a complementary tool rather than as input data for models. It is shown, thanks to two examples concerning the ball bearings and splines of the liquid hydrogen turbopump of the Vulcain engine, what can be expected from such techniques. Total exploitation of the results has still to be done, but preliminary results are quite encouraging. ESA

SHEAR BUCKLING OF FIBER METAL LAMINATES: COMPARISON BETWEEN ORTHOTROPIC AND ANISOTROPIC PLATE MODELS USING FINITE ELEMENT METHOD
S. Krishnakumar Jul. 1993 44 p
(LTR-ST-1934; CTN-93-60861) Avail: Issuing Activity (Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC)

The finite element method is used to compare the results provided by two approaches for the simulation of shear buckling of anisotropic fiber metal laminates, ARALL and GLARE. Two different load cases are studied: uniform shear stresses along the boundary, as is usually employed in theoretical analyses; and shear displacement along one edge of a plate, as is normally the case under test conditions. The orthotropic approximation yields solutions that are independent of the sign of the applied stresses and have only a mild variation with changes in the orientation of the reinforcing fibers. The influence of anisotropy is much larger in the case of applied shear displacement than in the uniform stress case, for all laminates except the pseudo-isotropic GLARE3 material. A reversal of the applied load direction can alter the buckling strength by a factor of 2.5 for this load condition. In unidirectional laminates subjected to in-plane shear displacement, the orthotropic model overestimates the buckling load by about 55 percent in some cases, and underestimates it by nearly 40 percent in others. In the case of GLARE3, the difference between the anisotropic solution and the orthotropic model is less than 2 percent.

AUTOFRETTAGE: STRESS DISTRIBUTION UNDER LOAD AND RETAINED STRESSES AFTER DEPRESSURIZATION. A MODIFIED PLANE-STRAIN CASE Final Technical Report
Boaz Avitzur Apr. 1993 63 p
(AD-A266320; ARCCB-TR-93015) Avail: CASI HC A04/MF A01

There is a long-standing interest in developing a capability to predict the distribution of retained stresses in thick-walled pressure vessels after the removal of an internal pressure--post autofrettage. The key to such a prediction is in the capacity to compute the stress distribution in a vessel while under externally imposed stress sufficient enough to cause at least partial plastic deformation. A good approximation of the stress distribution was developed by Mises in his 1913 plane-stress solution. The fact that such vessels are not representative of the plane-stress condition not withstanding, Mises recognized that his solution was mathematically restricted to a limited range of vessels' wall ratios. More recently, Avitzur offered a solution similar to that of Mises, but for a plane-strain condition. Depending on the material's Poisson's factor, Avitzur's solution is also mathematically applicable for a limited range of vessels' wall ratios only. The wall ratio, beyond which Avitzur's solution in plane-strain is not applicable, is a few

times larger than that which limits Mises' solution in plane-stress. This work introduces a modification to Avitzur's solution in plane-strain, which makes its applicability unlimited. DTIC

INVESTIGATION OF CRITERIA FOR DUCTILE FRACTURE UNDER FULLY-PLASTIC CONDITIONS Ph.D. Thesis
Robert Joseph Dexter 1992 387 p
Avail: Univ. Microfilms Order No. DA9309149

Under fully-plastic conditions, a plot of the J integral vs. crack extension (J-R curve) and other essentially equivalent approaches are excessively dependent on test specimen geometry and cannot be reliably used to predict tearing in full-scale members. Two alternative approaches were developed and tested in this research. Critical strain values (just prior to fracture) were estimated from large-deformation finite-element simulations of tensile tests. There was less than 12 percent variation in the critical strain values obtained from flat, round, and notched tensile specimens of a clean low-carbon pipeline steel. Application of the critical strain to tearing experiments required an accurate estimate of the three-dimensional strain field at a distance less than two millimeters from the crack tip and such a large-deformation analysis was impractical at this time. The three-dimensional strain field at a distance less than two millimeters from the crack tip and such a large deformation analysis was impractical at this time. The incremental generalization of the J integral (T*) was modified to calculate the energy dissipation rate in a small box including several layers of elements surrounding the crack tip. Because this modified T* parameter is calculated from the stresses and strains outside this box, this approach can be used with a small-strain two-dimensional analysis. The modified T* integral as well as the conventional J integral were calculated from such a small-strain simulation of tearing tests of two geometries for two pipeline steels. The calculated J-R curves were very close to the measured J-R curves and the slopes of these curves varied between specimens by more than 72 percent. A plot of the modified T* integral vs. crack extension was essentially constant with crack extension. The mean steady-state values varied between specimens by less than 45 percent, i.e. the modified T* integral during crack propagation was relatively independent of specimen geometry. Dissert. Abstr.

A STOCHASTIC MODEL FOR BEHAVIOR ANALYSIS OF FIBER-REINFORCED QUASI-BRITTLE MATERIALS Ph.D. Thesis
Artur Stanislaw Kurzydlo 1992 205 p
Avail: Univ. Microfilms Order No. DA9311941

Short fiber reinforced composites are established as a class of materials today. Modeling of such heterogeneous materials is still in the development stage. A proposed model which combines stochastic concepts with micromechanical approach is designed to predict the behavior of such materials. It is based on stochastic models for material behavior and combines the classical theory of deformation with a statistical treatment of imperfect materials. The model uses the principle of superposition of strain rates as a basis. Therefore such deformations as microcracking, plastic flow, thermoelastic behavior, and growth, coalescence and nucleation of voids, and crack-fiber interaction as well as most other kinds of inelastic behavior can be incorporated in the model. The stochastic material theory is expanded to predict a variety of uncertain material behavior. In the new model, such characteristics as random positions of fibers in the matrix, interactions between random cracks and fibers, change in the overall material behavior due to the changes in the structure of fibers and cracks during a loading process, deformation due to microcracking are treated by analyzing the 'open' and 'closed' cracks and considering the shearing of closed cracks. In this model, cracks are assumed to be circular (penny-shaped), and of random orientations and size, described by a probability density function. Available analytical solutions for the opening cracks and for the stability of penny-shaped cracks (both for tension and shear) are combined and included in the model to account for any arbitrary state of stress. Plastic flow is characterized by a kinematic-hardening model; and large deformations are accounted for through the polar decomposition theorem by separating them each into a stretch and a rotation component. Distinction between the fixed and rotating reference frames (which is crucial for isotropic materials) is also made; and elastic modulus is taken as a variable to account for the microcracking behavior. Dissert. Abstr.

N94-13596 Illinois Univ., Chicago.
FINITE ELEMENT ANALYSIS OF COMPOSITE PLATES BY USE OF MODIFIED COMPLEMENTARY ENERGY PRINCIPLE Ph.D. Thesis
Payman Afshari 1992 179 p
Avail: Univ. Microfilms Order No. DA9310117

Multilayered composite plates are of interest for a variety of structural application in such industries as automotive and aerospace where high strength to weight ratios are desirable. A composite plate can be distinguished from their single layered isotropic counterpart in that the transverse shear deformation plays a significant role in the structural behavior of the plate. This effect is present even for geometrically thin composite plate. The inclusion of transverse shear deformation, the extension-bending, twisting-extension and twisting-bending coupling effects that exist due to the different orthotropic material properties of each layer, requires a more sophisticated approach. A series of plate elements are formulated based on a variational principle, namely, Modified Complementary Energy. Mindlin thin plate theory is selected to govern the general characteristics and behavior of this type of structure. Transverse shear deformation is included in the formulation. A series of in-plane strain functions are assumed, from which the corresponding stresses for each lamina are determined. By satisfying the equilibrium equations, the transverse stresses are calculated. These elements are invariant and do not exhibit any shear locking in the thin plate limit. Also, no shear correction factor is included in the development of the formulation or the computer code. A FORTRAN code, CPLATE, is developed. Eight node isoparametric elements are utilized to describe the displacement field. Each node has five degrees of freedom, which are three displacements and two independent cross-sectional rotations. To identify the scope of application and limitations of these elements, several example problems are selected to cover a variety of geometrical and material properties. The outcome of the displacement and vibration analyses shows excellent agreement between the exact elasticity solutions and current formulation. Also, the predicted transverse shear stress profile and magnitude, using the present formulation, matched with those of the exact elasticity and high order plate theories, in the thin to moderately thick plate limit. Dissert. Abstr.

BOUNDARY FORMULATIONS FOR NONLINEAR DESIGN SENSITIVITY ANALYSIS Ph.D. Thesis
Hua Wang 1993 200 p
Avail: Univ. Microfilms Order No. DA9308244

This dissertation describes an investigation into the prospect of generating efficient and accurate boundary formulations for shape design sensitivity analysis (DSA) for nonlinear thermal and nonlinear structural problems. Theoretical formulations of DSA for thermal conduction problems with temperature dependent conductivity, temperature dependent convection, and radiation boundary conditions are developed. The temperature dependent conductivity problem is treated via a Kirchhoff transformation. Implicit differentiation of the discretized boundary integral equations governing the conduction of heat in solid objects subjected to nonlinear boundary conditions is shown to generate an accurate and economical approach for the computation of shape sensitivities for this class of problems. The computer algorithmic details for BEA and DSA for nonlinear thermal problems are presented and examined. Several iterative strategies are presented for the solution of the resulting sets of nonlinear equations and the computational performances are examined. Boundary formulations for shape DSA for solid mechanics problems exhibiting small strain elastoplastic behavior is also investigated. The theoretical formulation accounts for elastoplastic effects by the utilization of particular integrals. The computer algorithmic details for BEA and DSA for these nonlinear structural problems are developed and examined. An iterative strategie is presented for the solution of the resulting sets of nonlinear equations and the computational performances are examined. This particular integral approach to DSA for elastoplastic problems allots for the computation of response sensitivity without the need for domain discretization. Multi-zone modeling and zone condensation techniques are employed in the nonlinear thermal problems to improve the computational efficiency of nonlinear DSA for boundary element analysis (BEA) models with partial geometric sensitivity to design variables. It is demonstrated that the technique provides substantive computational economies in this process for models with either localized nonlinear boundary conditions or regions of geometric insensitivity to design

variables. A series of nonlinear thermal and structural examples that have analytical solutions are presented to quantify the accuracy of the formulations developed. Exact analytical expressions for shape sensitivities associated with these problems are developed and are compared with the sensitivities computed using the boundary element formulation. Dissert. Abstr.

AN EXPERT SYSTEM FOR INTEGRATED STRUCTURAL ANALYSIS AND DESIGN OPTIMIZATION FOR AEROSPACE STRUCTURES Final Technical Report
Apr. 1992 70 p
(Contract NAS3-25642; SBIR-04.04-1319)
(NASA-CR-194225; NAS 1.26:194225; SAT-380.02) Avail: CASI HC A04/MF A01

The results of a research study on the development of an expert system for integrated structural analysis and design optimization is presented. An Object Representation Language (ORL) was developed first in conjunction with a rule-based system. This ORL/AI shell was then used to develop expert systems to provide assistance with a variety of structural analysis and design optimization tasks, in conjunction with procedural modules for finite element structural analysis and design optimization. The main goal of the research study was to provide expertise, judgment, and reasoning capabilities in the aerospace structural design process. This will allow engineers performing structural analysis and design, even without extensive experience in the field, to develop error-free, efficient and reliable structural designs very rapidly and cost-effectively. This would not only improve the productivity of design engineers and analysts, but also significantly reduce time to completion of structural design. An extensive literature survey in the field of structural analysis, design optimization, artificial intelligence, and database management systems and their application to the structural design process was first performed. A feasibility study was then performed, and the architecture and the conceptual design for the integrated 'intelligent' structural analysis and design optimization software was then developed. An Object Representation Language (ORL), in conjunction with a rule-based system, was then developed using C++. Such an approach would improve the expressiveness for knowledge representation (especially for structural analysis and design applications), provide ability to build very large and practical expert systems, and provide an efficient way for storing knowledge. Functional specifications for the expert systems were then developed. The ORL/AI shell was then used to develop a variety of modules of expert systems for a variety of modeling, finite element analysis, and design optimization tasks in the integrated aerospace structural design process. These expert systems were developed to work in conjunction with procedural finite element structural analysis and design optimization modules (developed in-house at SAT, Inc.). The complete software, AutoDesign, so developed, can be used for integrated 'intelligent' structural analysis and design optimization. The software was beta-tested at a variety of companies, used by a range of engineers with different levels of background and expertise. Based on the feedback obtained by such users, conclusions were developed and are provided. Author (revised)

AN 8-NODE AXISYMMETRIC ACOUSTIC FINITE ELEMENT FOR NON-AXISYMMETRIC FLUID-STRUCTURE INTERACTION ANALYSIS
Magnus Alvelid Jan. 1993 62 p Sponsored in part by Swedish National Board for Industrial and Technical Development
(Contract ESTEC-9307/91/NL/PP(SC))
(FFA-TN-1993-03; ETN-93-94488) Avail: CASI HC A04/MF A01

Two acoustic elements were developed for use in calculations of axisymmetric geometries subject to nonaxisymmetric loading. One of the elements is an 8 noded continuum fluid element and the other is a corresponding 6 noded coupling element, needed in fluid structure interaction problems. The elements were incorporated into the ASKA Harmonic System (HS) which is a subsystem within the ASKA code. The concept in ASKA-HS relies on Fourier decomposition of the loading and displacement/pressure field. If the loading may be described with only a few terms, in the Fourier decomposition of the variation in the circumferential direction, the analysis method described requires considerably fewer degrees of freedom compared to a full three dimensional (3D) analysis for reaching the same accuracy. The elements were verified against corresponding 3D analyses for one uncoupled and one coupled problem. ESA

SOME COMPUTATIONAL TOOLS FOR THE ANALYSIS OF THROUGH CRACKS IN STIFFENED FUSELAGE SHELLS
C. C. Rankin (Lockheed Missiles and Space Co., Palo Alto, CA.), F. A. Brogan (Lockheed Missiles and Space Co., Palo Alto, CA.), and E. Riks Oct. 1992 24 p Original contains color illustrations
(LR-701; ETN-93-94419) Avail: CASI HC A03/MF A01

A method for computing the energy release rate for cracks of varying length in a typical stiffened metallic fuselage under general loading conditions is presented. Reliable analytical methods that predict the structural integrity and residual strength of aircraft fuselage structures containing cracks are needed to help to understand the behavior of pressurized stiffened shells with damage, to determine the safe life of such a shell. The models used in the simulation are derived from an extensive analysis of a fuselage barrel section subjected to operational flight loads. Energy release rates are computed as a function of the length of the crack, its location, and the crack propagation mode. ESA

THERMAL GRADIENT-INDUCED DEFLECTION OF A THICK-WALLED CYLINDER WITH BENDING RESIDUAL STRESSES Final Report
John H. Underwood and G. P. OHara Apr. 1993 21 p
(AD-A266347; ARCCB-TR-93017) Avail: CASI HC A03/MF A01

The interaction of a thermal gradient with bending residual stresses in a thick-walled cylinder is investigated using experimental measurements from prior work, mechanics analysis, and finite element stress analysis. A temperature gradient is applied to a cylinder containing residual stresses due to plastic bending resulting in transient elastic relaxation of the nonaxisymmetric residual stresses and bending of the cylinder. Analysis of the well-known similar problem in a rectangular bar is done first using solid mechanics solutions of ideal cases. Finite element calculations are made of the residual stresses following plastic bending of a thick-walled cylinder, the effects of a temperature distribution, and the resultant changes in stresses and strains and the associated tube bending. Results from the two approaches for a 200 C temperature gradient show a maximum angular displacement of 0.004 to 0.008 deg/m and the displacement returning to zero as the thermal gradient diminishes with time. MICROMECHANICAL DAMAGE THEORIES FOR BRITTLE SOLIDS WITH INTERACTING MICROCRACKS Final Report, 1 Sep. 1990 - 31 Aug. 1992
Jiann-Wen Ju 15 Mar. 1993 153 p
(Grant AF-AFOSR-0336-90)
(AD-A266348; AFOSR-93-0434TR) Avail: CASI HC A08/MF A02

Two-dimensional and three-dimensional statistical micromechanical damage models with randomly located interacting microcracks are presented to investigate the overall nonlinear mechanical responses of microcrack-weakened brittle solids. The macroscopic stress-strain relations of elastic solids with interacting micro-cracks are micromechanically derived by taking the ensemble average over all possible realizations. Several different approximate analytical solutions of a two-crack interaction model are introduced to account for micro-crack interaction among many randomly oriented and distributed microcracks. The overall elastic damage compliances of microcrack-weakened brittle solids are also derived by further taking the volume average of the ensemble-averaged stress-strain relations over the entire material mesostructural domain. Some special examples are investigated by using the proposed framework. At variance with existing phenomenological damage models, the proposed framework does not employ any fitted 'material parameters.' 'Cleavage 1' microcrack growth and 'evolutionary damage models' within the proposed context are also presented. DTIC

ON THE ORTHOTROPICITY ASSUMPTION AND DISCONTINUITY CONDITIONS OF CONICAL SHELLS
Guo Qi Zhang, Menahem Baruch, and Johann Arbocz Jun. 1992 14 p
(LR-703; ETN-93-94420) Avail: CASI HC A03/MF A01

The existence or nonexistence of the classical orthotropicity assumption for conical shells is examined. It is shown that an orthotropic shell with constant stiffness coefficients can not be achieved by using manufacturing techniques of composite materials. An approximation of such a shell can be obtained by using a special kind of stiffness. For the case of axially loaded orthotropic conical shells, buckling loads lower than the ones published in the literature are obtained. The discontinuous transition from conical to cylindrical shells for a case of classical boundary conditions is reexamined. ESA

FATIGUE AND RESIDUAL STRENGTH CHARACTERISTICS OF FIBER METAL LAMINATES SUBJECTED TO INCIDENTAL DAMAGE

Robert Fredell, Ad Vlot, and Marc Verbruggen (Structural Laminates Co., Alcoa Center, PA.) Dec. 1992 23 p Presented at 1992 USAF Aircraft Structural Integrity Program Conference, San Antonio, TX, 1-3 Dec. 1992
(LR-708; ETN-93-94425) Avail: CASI HC A03/MF A01

The fatigue and residual strength characteristics of the fiber metal laminates GLARE and ARALL, following damage typically encountered in the service environment, were investigated. Comparative impact tests showed a gereral trend of increasing impact resistance from carbon thermoplastic composites (poorest) to ARALL, monolithic aluminum 2024-T3, and GLARE 3 (best). Fatigue and residual strength tests carried out on impact and scratch damaged fiber metal laminates demonstrated the excellent tolerance of laminates to in-service damage. The extremely slow crack growth characteristics of laminates were not deteriorated by scratches. Impacts which caused perforations in GLARE and ARALL continued to exhibit the extremely slow fatigue crack growth for which the laminates are known. Repair criteria based on the blunt notch strength of the laminates have been proposed for in-service damage to riveted fiber metal laminate structures. Techniques used for the repair of aluminium structures can apply to laminates. ESA

TORSION PROBLEM OF ELASTOSTATICS: AN APPLICATION OF BOUNDARY ELEMENT METHOD AND RELATION WITH CONFORMAL MAPPING

Thomas S. Z. Hu Sep. 1992 32 p
(DSIS-92-03794; DREA-TM-92-218; CTN-93-60769) Avail: CASI HC A03

The boundary integral equation method can be applied to the solution of many types of partial differential equations which arise in mathematical physics. The governing equations of the torsion problem in elastostatics can be simplified to either Laplace's equation or Poisson's equation, and the boundary integral techniques developed for solving potential flow can be applied. The boundary integral formulation of Laplace's equation and its discretization are presented. The physical meaning of such equations is demonstrated through the application of the boundary element method to the torsion problem. The inaccuracy of the solutions at the corners of the domain is studied via the theory of conformal mapping. The method of conformal transformation is shown to be a useful tool in dealing with numerical difficulties. Author (CISTI)

VARIATIONAL APPROACH TO PROBABILISTIC FINITE ELEMENTS Final Report

T. Belytschko, W. K. Liu, A. Mani, and G. Besterfield Aug. 1991 177 p
(Grant NAG3-535; RTOP 505-63-5B)
(NASA-CR-187179; NAS 1.26:187179) Avail: CASI HC A09/MF A02

Probabilistic finite element methods (PFEM), synthesizing the power of finite element methods with second-moment techniques, are formulated for various classes of problems in structural and solid mechanics. Time-invariant random materials, geometric properties and loads are incorporated in terms of their fundamental statistics viz. second-moments. Analogous to the discretization of the displacement field in finite element methods, the random fields are also discretized. Preserving the conceptual simplicity, the response moments are calculated with minimal computations. By incorporating certain computational techniques, these methods are shown to be capable of handling large systems with many sources of uncertainties. By construction, these methods are applicable when the scale of randomness is not very large and when the probabilistic density functions have decaying tails. The accuracy and efficiency of these methods, along with their limitations, are demonstrated by various applications. Results obtained are compared with those of Monte Carlo simulation and it is shown that good accuracy can be obtained for both linear and nonlinear problems. The methods are amenable to implementation in deterministic FEM based computer codes. Author

CONTRIBUTION TO COMPARISON OF METHODS FOR DETERMINING WELDING PROCEDURES FOR THE AVOIDANCE OF HYDROGEN CRACKING

Risto A. Karppi and Pekka Nevasmaa Aug. 1992 52 p
(VTT-PUBS-107; IIW-IX-1673-92; ISBN-9-51-384225-8; ETN-93-94481)
Copyright Avail: CASI HC A04/MF A01

The method named VTT/OU (acronym for the Technical Center of Finland (VTT) and the Osaka University (OU)) is described. The VTT/OU method is based on the comparison of two values of the stress field parameter sigma(sub I) at the crack initiation area. The required value of sigma(sub I) is assessed by the restraint of the structure and the joint geometry. The attainable level of sigma(sub I) is determined by the steel composition, conditions were determined by the VTT/OU method in terms of minimum arc energy without preheat, and minimum preheat for three arc energies: 1,2, and 3 kJ/mm. As parameters, the hydrogen level, joint type (butt and fillet) and plate thickness were varied. The VTT/OU method was shown to take a somewhat different stand from the others on the importance of crack controlling factors. The joint geometry, especially with butt joints, is regarded as an essential factor affecting the level of precautions necessary. The VTT/OU method considers the use of low hydrogen electrodes and hydrogen removal by preheating above 100C more effective. For the fillet welds, the VTT/OU method is found to agree very well with CTS test results. ESA

THE NUMERICAL SIMULATION OF THE COLLAPSE PROCESS OF AXIALLY COMPRESSED CYLINDRICAL SHELLS WITH MEASURED IMPERFECTIONS

E. Riks, C. C. Rankin, and F. A. Brogan 1992 10 p Original contains color illustrations
(LR-705; ETN-93-94422) Avail: CASI HC A02/MF A01

A numerical computation of the collapse process of a cylindrical shell under prescribed edge displacement is discussed. The shell chosen for the computational experiment was manufactured, measured, and tested some twenty years ago. The purpose of the study is to compute the static, pre-collapse loading path and the subsequent snap (dynamic process) to the post buckling state. The test specimen is an integrally machined stringer stiffened cylindrical shell. The wave pattern in the pre-collapse state was observed to be dominated by a mode of one half wave in the axial direction and 9 waves in the circumferential direction. In the post buckling state after the snap, one half wave in the axial direction and ten full waves in the circumferential direction were observed. The simplifications applied in the model concern the adaptation of symmetry in the imperfection pattern and deformation after the load is applied. ESA

DEVELOPMENT OF TEST TECHNIQUES TO SIMULATE HIGH-FREQUENCY MECHANICAL SHOCK ON WEAPON COMPONENTS Final Report

Larry F. Thorne, John E. Britt, and Robert D. Jump Feb. 1993 29 p Original contains color illustrations

(Contract DE-AC04-76DP-00613)

(KCP-613-4998) Avail: CASI HC A03/MF A01

A test capability has been developed to subject components to high-level pyro-shock testing. Oscillatory-type shock pulses can be produced that simulate structural responses. The project culminated in the design and fabrication of an airgun facility. The airgun fires 3-inch-diameter projectiles weighing up to 40 pounds into large aluminum fixture plates. The plates are designed to resonate at a predetermined frequency and produce oscillatory acceleration-time waveforms which are transmitted to mounted samples. Shock response spectra (SRS) calculated from these waveforms verify compliance with the shock requirements. Author

ELASTIC-PLASTIC MIXED-ITERATIVE FINITE ELEMENT ANALYSIS: IMPLEMENTATION AND PERFORMANCE ASSESSMENT

Edhi Sutjahjo (Sverdrup Technology, Inc., Brook Park, OH.) and Christos C. Chamis May 1993 39 p

(RTOP 505-63-53)

(NASA-TM-106164; E-7864; NAS 1.15:106164) Avail: CASI HC A03/MF A01

An elastic-plastic algorithm based on Von Mises and associative flow criteria is implemented in MHOST-a mixed iterative finite element analysis computer program developed by NASA Lewis Research Center. The performance of the resulting elastic-plastic mixed-iterative analysis is examined through a set of convergence studies. Membrane and bending behaviors of 4-node quadrilateral shell finite elements are tested for elastic-plastic performance. Generally, the membrane results are excellent, indicating the implementation of elastic-plastic mixed-iterative analysis is appropriate. Author

A SURVEY OF CRACK PATH STABILITY CRITERIA AND THEIR APPLICATION TO CRACK FLAPPING PHENOMENA IN STIFFENED STRUCTURES

K. J. J. M. Zaal Sep. 1992 153 p

(LR-681; ETN-93-94005) Avail: CASI HC A08/MF A02

In unstiffened and stiffened cylindrical shells, longitudinal cracks are known to flap. Above a certain length, the cracks no longer propagate in the longitudinal direction but turn towards a circumferentially oriented direction. In a pressurized fuselage, this type of U shaped crack could enable a controlled decompression in case of accidental damage or rapid growth of a fatigue crack. Both the T stress criterion of Cotterell and Rice and the criterion of Finnie and Saith can predict the directional stability of the path a crack is following. The predictions of both criteria to experimental results of Swift are compared. The crack path stability criterion of Finnie and Saith seems to emerge as the best available crack path stability criterion. The criterion is material dependent. In combination with a geometrical nonlinear finite element analysis, it may be the first candidate for someone studying directional stability of cracks. ESA

COMPRESSIVE BUCKLING OF CURVED, ANISOTROPIC PANELS STIFFENED IN TWO DIRECTIONS. PART 1: DERIVATION OF THE GOVERNING EQUATIONS

J. L. Verolme Aug. 1992 44 p

(LR-694; ETN-93-94006) Avail: CASI HC A03/MF A01

A designer's tool for calculating the compressive buckling of aircraft fuselage panels is described. The technique applied is an extension of the adjacent equilibrium criterion from which information about the initial postbuckling behavior is obtained. The basic equations, on which most of the modules of the tool are based, are derived using the energy method. Stability equations in the out of plane coordinate and Airy's stress function, together with jump and boundary conditions, are obtained. The assumptions made are listed. The physical behavior of fuselage panels in compression is treated. ESA

AN EXPERIMENTAL INVESTIGATION INTO THE DAMAGE RESISTANCE AND COMPRESSION-AFTER-IMPACT STRENGTH OF T800H/3900-2

H. Vietinghoff, C. Poon (Institute for Aerospace Research, Ottawa, Ontario.), P. V. Straznicky, and R. Gould (Institute for Aerospace Research, Ottawa, Ontario.) Jan. 1993 93 p Original contains color illustrations

(LTR-ST-1909; CTN-93-60764) Avail: CASI HC A05/MF A01

An experimental investigation was conducted into impact behavior of a Toray T800H/3900-2 material system, a system representative of the most recent generation of toughened graphite-epoxy composites selected for use in several new airframes. In the investigation, test specimens featuring quasi-isotropic and midplane symmetric layup with 24 plies were fabricated and impacted at five different impact energy levels, resulting in damage ranging from barely visible to severe. Damage was characterized using nondestructive and destructive inspection, including ultrasound and x-ray techniques, and the specimens were then compressively loaded to failure. The carefully controlled set of experiments resulted in a detailed three dimensional characterization of the damage induced in the selected laminate layup for a range of impact energies. Compression after impact testing resulted in a correlation of impact energy and damage area with residual compressive strength. The results will be used to calibrate and test the analytical prediction methods being developed as part of a project on impact resistance and tolerance of composite materials, and as reference data on the material system. MSD IN FUSELAGE LAP JOINTS: REQUIREMENTS FOR INSPECTION INTERVALS FOR TYPICAL FUSELAGE LAP JOINT PANELS WITH MULTIPLE SITE DAMAGE M.S. Thesis

G. P. Wit Jul. 1992 160 p

(LR-697; ETN-93-94009) Avail: CASI HC A08/MF A02

Inspection of failed aircraft structures and fractography on fatigue specimens showed that after a high number of flights, cracks can appear simultaneously in riveted lap joints. When these crack tips approach each other, a mutual interaction causes an unexpected fast crack growth and new coalescence of cracks. The term Multiple Site Damage (MSD) is used when the mutual interaction of two or more damages is noticeable. A model to predict the fatigue life of a riveted lap joint and the minimum necessary inspection interval for safe aircraft operation is presented. The program was developed to simulate the fatigue process and aircraft inspection. Input for this analysis are scatter data for initiation, the stress distribution between frames and the geometry of the structure. Methods that can be used to avoid accidents due to MSD are reviewed. A test program to support the analysis is described. ESA

FINITE ELEMENT CALCULATION OF STRESS-INTENSITY FACTORS FOR THRU-THICKNESS CRACKS IN DEN SPECIMENS

W. Beres and A. K. Koul Nov. 1992 35 p

(LTR-ST-1905; CTN-93-60765) Avail: CASI HC A03/MF A01

The accepted techniques for stress intensity factor (SIF) extraction from finite element method (FEM) calculation results are reviewed. Results are then summarized for through-thickness cracks emanating from a semicircular notch surface of double edge notch (DEN) specimens of two different geometries corresponding to AGARD and Institute of Aerospace Research dimensions. The AGARD specimen has a notch radius to specimen width ratio (R/W) of 1/16 and the other has a R/W of 1/8. Two-dimensional FEM models were run on NISA 2/DISPLAY 2 and ABAQUS FEM software packages to calculate SIF's. Results based on the models of Yamamoto (1974), Schijve (1982), Newman (1990), and Kujawski (1991) are compared and the effect of R/W on the SIF of small through-thickness cracks in DEN specimens are assessed. Among all empirical models analyzed, Kujawski's predictions provide the best fit with the FEM results. Yamamoto's model provides the best fit for crack lengths in the 0.8 to 1.0 mm range. Relative to a single crack in only one notch of the DEN specimen, the presence of two cracks (one at each notch root) does not significantly influence the SIF values. A change in R/W significantly influences the SIF values: above a crack length of 0.3 mm, an increase of R/W from 1/16 to 1/8 increases the SIF by about 28 percent. Below this length the percentage difference in SIF is lower. Author (CISTI)

HIERARCHICAL NONLINEAR BEHAVIOR OF HOT COMPOSITE STRUCTURES

P. L. N. Murthy, C. C. Chamis, and S. N. Singhal (Sverdrup Technology, Inc., Brook Park, OH.) Jun. 1993 20 p Presented at the First Joint SES, ASME, and ASCE Meeting, Charlottesville, VA, 7-9 Jun. 1993
(RTOP 505-63-5B)
(NASA-TM-106229; E-7947; NAS 1.15:106229) Avail: CASI HC A03/MF A01

Hierarchical computational procedures are described to simulate the multiple scale thermal/mechanical behavior of high temperature metal matrix composites (HT-MMC) in the following three broad areas: (1) behavior of HT-MMC's from micromechanics to laminate via METCAN (Metal Matrix Composite Analyzer), (2) tailoring of HT-MMC behavior for optimum specific performance via MMLT (Metal Matrix Laminate Tailoring), and (3) HT-MMC structural response for hot structural components via HITCAN (High Temperature Composite Analyzer). Representative results from each area are presented to illustrate the effectiveness of computational simulation procedures and accompanying computer codes. The sample case results show that METCAN can be used to simulate material behavior such as the entire creep span; MMLT can be used to concurrently tailor the fabrication process and the interphase layer for optimum performance such as minimum residual stresses; and HITCAN can be used to predict the structural behavior such as the deformed shape due to component fabrication. These codes constitute virtual portable desk-top test laboratories for characterizing HT-MMC laminates, tailoring the fabrication process, and qualifying structural components made from them. Author

PROBABILISTIC MICROMECHANICS FOR HIGH-TEMPERATURE COMPOSITES Final Report

J. N. Reddy Sep. 1993 45 p
(Grant NAG3-933; RTOP 510-01-50)
(NASA-CR-191150; E-8113; NAS 1.26:191150) Avail: CASI HC A03/MF A01

The three-year program of research had the following technical objectives: the development of probabilistic methods for micromechanics-based constitutive and failure models, application of the probabilistic methodology in the evaluation of various composite materials and simulation of expected uncertainties in unidirectional fiber composite properties, and influence of the uncertainties in composite properties on the structural response. The first year of research was devoted to the development of probabilistic methodology for micromechanics models. The second year of research focused on the evaluation of the Chamis-Hopkins constitutive model and Aboudi constitutive model using the methodology developed in the first year of research. The third year of research was devoted to the development of probabilistic finite element analysis procedures for laminated composite plate and shell structures. Author

PREDICTING THE VIBRATIONS OF A SPINNING INFLATED MEMBRANE

D. J. Segalman and A. Slavin 1993 14 p Presented at the Conference on Vibration and Noise, Albuquerque, NM, 20-22 Sep. 1993
(Contract DE-AC04-76DP-00789)
(DE93-010690; SAND-92-2240C; CONF-9309116-2) Avail: CASI HC A03/MF A01

The primary difficulty of computing the vibration of spinning inflated membranes arises from the low natural frequencies of such systems. When such systems are rotated near their own natural frequencies the dynamics equations must account for higher order kinematics than is necessary for more rigid structures. These complications results from the membrane loads that develop within the bodies in reaction to the accelerations of the overall body. When second order kinematics act against these membrane loads, the resulting energies become of the same order as the potential and kinetic energies of the vibrations that would be calculated by first order kinematics. These complications apply to the problem addressed here. We consider a spin-stabilized, inflated membrane, spinning around its minor axis. This structure is very flexible and somewhat viscoelastic, so vibrations excited by the overall motion of the structure will dissipate energy of the system, thus, reducing the kinetic energy. A reduction in kinetic energy consistent with a conservation of angular momentum results in coning and, eventually, tumbling. Here we must address the excitation of vibration by the rigid-body motion and then we must address the retarding effect of the energy dissipation on the rigid-body motion. DOE

SOME FREQUENCY AND DAMPING MEASUREMENTS OF LAMINATED BERYLLIUM BEAMS

J. Andriulli and L. C. Rogers 1993 7 p Presented at the Damping 1993, San Francisco, CA, 24-26 Feb. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015909; CONF-9302129-1) Avail: CASI HC A02/MF A01

A quantum leap in vibration performance of beryllium structure has been experimentally investigated. Laminations, segmentation, and sandwich syntactic foam core have been demonstrated to have both high specific flexural structural stiffness and high damping for reduced vibratory response. Acquisition cost, weight, machinability, and environmental benefits are also expected. Applications to the structure of optical and inertial navigation equipment would lead to reductions in jitter levels and other vibratory response measures. DOE

DYNAMIC SOIL PRESSURES ON RIGID CYLINDRICAL VAULTS

A. S. Veletsos (Rice Univ., Houston, TX.) and A. H. Younan (Rice Univ., Houston, TX.) Feb. 1993 57 p
(Contract DE-AC02-76CH-00016)
(DE93-013930; BNL-52372) Avail: CASI HC A04/MF A01

A critical evaluation is made of the dynamic pressures and the associated forces induced by ground shaking on an upright, circular, rigid vault that is embedded in a uniform viscoelastic stratum of constant thickness and infinite extent in the horizontal plane. Both the vault and the stratum are presumed to be supported on a non- deformable base undergoing a space-invariant, uniform horizontal motion. The effects of both harmonic and earthquake-induced excitations are examined. Simple approximate expressions for the responses of the system are formulated, and comprehensive numerical data are presented which elucidate the underlying response mechanisms and the effects and relative importance of the various parameters involved. The parameters investigated include the height to radius ratio for the vault, the conditions at the vault-medium interface, and the material properties of the stratum. In addition to valuable insights into the response of the particular system being examined, the results presented provide a conceptual framework for the analysis and interpretation of solutions for more involved systems as well. DIFFERENTIAL SENSITIVITY THEORY APPLIED TO THE MESA CODE FOR HIGH PRESSURE INTERACTIONS

P. J. Maudlin, R. J. Henninger, and E. N. Harstad 1993 13 p Presented at the 14th International Conference on High Pressure Science and Technology and 1993 Technical Meeting of the Topical Group on Shock

Compression of Condensed Matter, Colorado Springs, CO, 28 Jun. - 3 Jul. 1993
(Contract W-7405-eng-36)
(DE93-016460; LA-UR-93-2323; CONF-9306167-5) Avail: CASI HC A03/MF A01

A technique called Differential Sensitivity Theory (DST) is applied to the system of equations solved by the MESA hydrocode. DST uses adjoint techniques to determine exact sensitivity derivatives, i.e., if R is a calculational result of interest (response R) and alpha(sub i) is a calculational input (parameter alpha(sub i)), then (partial derivative)R/(partial derivative)alpha(sub i) is defined as the sensitivity. The advantage of using DST is that for an n-parameter problem all n sensitivities can be obtained by integrating the solutions from only two calculations, a MESA calculation and its corresponding adjoint calculation using an Adjoint Continuum Mechanics code (ACM). This work describes the derivation and solution of the appropriate set of adjoint and sensitivity equations for the purpose of computing sensitivities for high-rate two-dimensional, multi-component, high deformation problems. As an example, results are presented for a flyer plate problem. DOE

The Fifth Annual Workshop on Aerospace Computational Control was one in a series of workshops sponsored by NASA, NSF, and the DOD. The purpose of these workshops is to address computational issues in the analysis, design, and testing of flexible multibody control systems for aerospace applications. The intention in holding these workshops is to bring together users, researchers, and developers of computational tools in aerospace systems (spacecraft, space robotics, aerospace transportation vehicles, etc.) for the purpose of exchanging ideas on the state of the art in computational tools and techniques. For individual titles, see N94-14619 through N94-14652.

GEOMETRIC STIFFENING IN MULTIBODY DYNAMICS FORMULATIONS
Inna Sharf *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 1-24 Sponsored by Natural Sciences and Engineering Research Council (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

In this paper we discuss the issue of geometric stiffening as it arises in the context of multibody dynamics. This topic has been treated in a number of previous publications in this journal and appears to be a debated subject. The controversy revolves primarily around the 'correct' methodology for incorporating the stiffening effect into dynamics formulations. The main goal of this work is to present the different approaches that have been developed for this problem through an in-depth review of several publications dealing with this subject. This is done with the goal of contributing to a precise understanding of the existing methodologies for modelling the stiffening effects in multibody systems. Thus, in presenting the material we attempt to illuminate the key characteristics of the various methods as well as show how they relate to each other. In addition, we offer a number of novel insights and clarifying interpretations of these schemes. The paper is completed with a general classification and comparison of the different approaches. STRESS STIFFENING AND APPROXIMATE EQUATIONS IN FLEXIBLE MULTIBODY DYNAMICS
Carlos E. Padilla and Andreas H. vonFlotow (Massachusetts Inst. of Tech., Cambridge.) *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 25-35 See also A92-55169 (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

A useful model for open chains of flexible bodies undergoing large rigid body motions, but small elastic deformations, is one in which the equations of motion are linearized in the small elastic deformations and deformation rates. For slow rigid body motions, the correctly linearized, or consistent, set of equations can be compared to prematurely linearized, or inconsistent, equations and to 'oversimplified,' or ruthless, equations through the use of open loop dynamic simulations. It has been shown that the inconsistent model should never be used, while the ruthless model should be used whenever possible. The consistent and inconsistent models differ by stress stiffening terms. These are due to zeroth-order stresses effecting virtual work via nonlinear strain-displacement terms. In this paper we examine in detail the nature of these stress stiffening terms and conclude that they are significant only when the associated zeroth-order stresses approach 'buckling' stresses. Finally it is emphasized that when the stress stiffening terms are negligible the ruthlessly linearized equations should be used. Author (revised)

A COMPONENT MODES PROJECTION AND ASSEMBLY MODEL REDUCTION METHODOLOGY FOR ARTICULATED, MULTI-FLEXIBLE BODY STRUCTURES
Allan Y. Lee and Walter S. Tsuha *In its* Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 55-75 See also A92-55168 (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

A two-stage model reduction methodology, combining the classical Component Mode Synthesis (CMS) method and the newly developed Enhanced Projection and Assembly (EP&A) method, is proposed in this research. The first stage of this methodology, called the COmponent Modes Projection and Assembly model REduction (COMPARE) method, involves the generation of CMS mode sets, such as the MacNeal-Rubin mode sets. These mode sets are then used to reduce the order of each component model in the Rayleigh-Ritz sense. The resultant component models are then combined to generate reduced-order system models at various system configurations. A composite mode set which retains important system modes at all system configurations is then selected from these reduced-order system models. In the second stage, the EP&A model reduction method is employed to reduce further the order of the system model generated in the first stage. The effectiveness of the COMPARE methodology has been successfully demonstrated on a high-order, finite-element model of the cruise-configured Galileo spacecraft. Author

APPLICATIONS OF COMPUTER ALGEBRA TO DISTRIBUTED PARAMETER SYSTEMS
Joel A. Storch *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 77-90 (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

In the analysis of vibrations of continuous elastic systems, one often encounters complicated transcendental equations with roots directly related to the system's natural frequencies. Typically, these equations contain system

parameters whose values must be specified before a numerical solution can be obtained. The present paper presents a method whereby the fundamental frequency can be obtained in analytical form to any desired degree of accuracy. The method is based upon truncation of rapidly converging series involving inverse powers of the system natural frequencies. A straightforward method to developing these series and summing them in closed form is presented. It is demonstrated how Computer Algebra can be exploited to perform the intricate analytical procedures which otherwise would render the technique difficult to apply in practice. We illustrate the method by developing two analytical approximations to the fundamental frequency of a vibrating cantilever carrying a rigid tip body. The results are compared to the numerical solution of the exact (transcendental) frequency equation over a range of system parameters. Author

COMPUTATIONAL CONTROLS WORKSTATION: ALGORITHMS AND HARDWARE **c60**

R. Venugopal and M. Kumar *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 117-123 (For primary document see N94-14618 02-39)

Avail: CASI HC A02/MF A04

The Computational Controls Workstation provides an integrated environment for the modeling, simulation, and analysis of Space Station dynamics and control. Using highly efficient computational algorithms combined with a fast parallel processing architecture, the workstation makes real-time simulation of flexible body models of the Space Station possible. A consistent, user-friendly interface and state-of-the-art post-processing options are combined with powerful analysis tools and model databases to provide users with a complete environment for Space Station dynamics and control analysis. The software tools available include a solid modeler, graphical data entry tool, O(n) algorithm-based multi-flexible body simulation, and 2D/3D post-processors. This paper describes the architecture of the workstation while a companion paper describes performance and user perspectives. Author

ASTEC AND MODEL: CONTROLS SOFTWARE DEVELOPMENT AT GODDARD SPACE FLIGHT CENTER **c61**

John P. Downing, Frank H. Bauer, and Jeffrey L. Surber (Fairchild Space Co., Germantown, MD.) *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 131-141 (For primary document see N94-14618 02-39)

Avail: CASI HC A03/MF A04

The ASTEC (Analysis and Simulation Tools for Engineering Controls) software is under development at the Goddard Space Flight Center (GSFC). The design goal is to provide a wide selection of controls analysis tools at the personal computer level, as well as the capability to upload compute-intensive jobs to a mainframe or supercomputer. In the last three years the ASTEC (Analysis and Simulation Tools for Engineering Controls) software has been under development. ASTEC is meant to be an integrated collection of controls analysis tools for use at the desktop level. MODEL (Multi-Optimal Differential Equation Language) is a translator that converts programs written in the MODEL language to FORTRAN. An upgraded version of the MODEL program will be merged into ASTEC. MODEL has not been modified since 1981 and has not kept with changes in computers or user interface techniques. This paper describes the changes made to MODEL in order to make it useful in the 90's and how it relates to ASTEC. Author (revised)

ANIMATION OF MULTI-FLEXIBLE BODY SYSTEMS AND ITS USE IN CONTROL SYSTEM DESIGN **c61**

Carl Juengst and Ron Stahlberg (Iowa Univ., Iowa City.) *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 143-151 (For primary document see N94-14618 02-39)

Avail: CASI HC A02/MF A04

Animation can greatly assist the structural dynamicist and control system analyst with better understanding of how multi-flexible body systems behave. For multi-flexible body systems, the structural characteristics (mode frequencies, mode shapes, and damping) change, sometimes dramatically with large angles of rotation between bodies. With computer animation, the analyst can visualize these changes and how the system responds to active control forces and torques. A characterization of the type of system we wish to animate is presented. The lack of clear understanding of the above effects was a key element leading to the development of a multi-flexible body animation software package. The resulting animation software is described in some detail here, followed by its application to the control system analyst. Other applications of this software can be determined on an individual need basis. A number of software products are currently available that make the high-speed rendering of rigid body mechanical system simulation possible. However, such options are not available for use in rendering flexible body mechanical system simulations. The desire for a high-speed flexible body visualization tool led to the development of the Flexible Or Rigid Mechanical System (FORMS) software. This software was developed at the Center for Simulation and Design Optimization of Mechanical Systems at the University of Iowa. FORMS provides interactive high-speed rendering of flexible and/or rigid body mechanical system simulations, and combines geometry and motion information to produce animated output. FORMS is designed to be both portable and flexible, and supports a number of different user interfaces and graphical display devices. Additional features have been added to FORMS that allow special visualization results related to the nature of the flexible body geometric representations. Author (revised)

THE USE OF LINKED LISTS IN THE SIMULATION OF CONTROLLER-STRUCTURE INTERACTION **c61**
Ralph Quan *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 153-166 See also A93-44533 (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

An algorithm for the computer simulation of large space structures under active control is considered. Linked lists are used in a matrix data structure to implement the trapezoidal rule on the system differential equations. The use of the trapezoidal rule ensures that the numerical stability is equivalent to the system stability, which is essential for this type of simulation. The sparsity of the system matrices is exploited by the linked lists, and the algorithm efficiently steps through the lists in an orderly fashion. Results of simulations on a NASA large space structure experiment are reported. Author

This paper presents an approach to modeling the dynamics of flexible multibody systems such as flexible spacecraft and limber space robotic systems. A large number of degrees of freedom and complex dynamic interactions are typical in these systems. This paper uses spatial operators to develop efficient recursive algorithms for the dynamics of these systems. This approach very efficiently manages complexity by means of a hierarchy of mathematical operations. Author

NONRECURSIVE FORMULATIONS OF MULTIBODY DYNAMICS AND CONCURRENT MULTIPROCESSING
Andrew J. Kurdila and Ramesh Menon *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 185-204 (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

Since the late 1980's, research in recursive formulations of multibody dynamics has flourished. Historically, much of this research can be traced to applications of low dimensionality in mechanism and vehicle dynamics. Indeed, there is little doubt that recursive order N methods are the method of choice for this class of systems. This approach has the advantage that a minimal number of coordinates are utilized, parallelism can be induced for certain system topologies, and the method is of order N computational cost for systems of N rigid bodies. Despite the fact that many authors have dismissed redundant coordinate formulations as being of order N(exp 3), and hence less attractive than recursive formulations, we present recent research that demonstrates that at least three distinct classes of redundant, nonrecursive multibody formulations consistently achieve order N computational cost for systems of rigid and/or flexible bodies. These formulations are as follows: (1) the preconditioned range space formulation; (2) penalty methods; and (3) augmented Lagrangian methods for nonlinear multibody dynamics. The first method can be traced to its foundation in equality constrained quadratic optimization, while the last two methods have been studied extensively in the context of coercive variational boundary value problems in computational mechanics. Until recently, however, they have not been investigated in the context of multibody simulation, and present theoretical questions unique to nonlinear dynamics. All of these nonrecursive methods have additional advantages with respect to recursive order N methods: (1) the formalisms retain the highly desirable order N computational cost; (2) the techniques are amenable to concurrent simulation strategies; (3) the approaches do not depend upon system topology to induce concurrency; and (4) the methods can be derived to balance the computational load automatically on concurrent multiprocessors. In addition to the presentation of the fundamental formulations, this paper presents new theoretical results regarding the rate of convergence of order N constraint stabilization schemes associated with the newly introduced class of methods. NON-RECURSIVE AUGMENTED LAGRANGIAN ALGORITHMS FOR THE FORWARD AND INVERSE DYNAMICS OF CONSTRAINED FLEXIBLE MULTIBODIES
Eduardo Bayo and Ragnar Ledesma *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 205-219 Sponsored in part by TRW, Inc. (For primary document see N94-14618 02-39)
(Contract F49620-91-C-0095)
Avail: CASI HC A03/MF A04

A technique is presented for solving the inverse dynamics of flexible planar multibody systems. This technique yields the non-causal joint efforts (inverse dynamics) as well as the internal states (inverse kinematics) that produce a prescribed nominal trajectory of the end effector. A non-recursive global Lagrangian approach is used in formulating the equations for motion as well as in solving the inverse dynamics equations. Contrary to the recursive method previously presented, the proposed method solves the inverse problem in a systematic and direct manner for both open-chain as well as closed-chain configurations. Numerical simulation shows that the proposed procedure provides an excellent tracking of the desired end effector trajectory. Author

A NEURAL-NETWORK APPROACH TO ROBOTIC CONTROL **c63**
D. P. W. Graham and G. M. T. DEleuterio *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 221-236 Sponsored by Natural Science and Engineering Research Council; Inst. for Robotics and Intelligent Systems; Inst. for Space and Terrestrial Science (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

An artificial neural-network paradigm for the control of robotic systems is presented. The approach is based on the Cerebellar Model Articulation Controller created by James Albus and incorporates several extensions. First, recognizing the essential structure of multibody equations of motion, two parallel modules are used that directly reflect the dynamical characteristics of multibody systems. Second, the architecture of the proposed network is imbued with a self-organizational capability which improves efficiency and accuracy. Also, the networks can be arranged in hierarchical fashion with each subsequent network providing finer and finer resolution. Author

COMPUTATIONAL STRATEGIES IN THE DYNAMIC SIMULATION OF CONSTRAINED FLEXIBLE MBS
F. M. L. Amirouche and M. Xie *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 237-241 (For primary document see N94-14618 02-39)
Avail: CASI HC A01/MF A04

This research focuses on the computational dynamics of flexible constrained multibody systems. At first a recursive mapping formulation of the kinematical expressions in a minimum dimension as well as the matrix representation of the equations of motion are presented. The method employs Kane's equation, FEM, and concepts of continuum mechanics. The generalized active forces are extended to include the effects of high temperature conditions, such as creep, thermal stress, and elastic-plastic deformation. The time variant constraint relations for rolling/contact conditions between two flexible bodies are also studied. The constraints for validation of MBS simulation of gear meshing contact using a modified Timoshenko beam theory are also presented. The last part deals with minimization of vibration/deformation of the elastic beam in multibody systems making use of time variant boundary conditions. The above methodologies and computational procedures developed are being implemented in a program called DYAMUS. Author (revised)

PARALLEL O(LOG n) ALGORITHMS FOR OPEN- AND CLOSED-CHAIN RIGID MULTIBODY SYSTEMS BASED ON A NEW MASS MATRIX FACTORIZATION TECHNIQUE **c61**
Amir Fijany *In its* Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 243-266 (For

primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

In this paper, parallel O(log n) algorithms for computation of rigid multibody dynamics are developed. These parallel algorithms are derived by parallelization of new O(n) algorithms for the problem. The underlying feature of these O(n) algorithms is a drastically different strategy for decomposition of interbody force which leads to a new factorization of the mass matrix (M). Specifically, it is shown that a factorization of the inverse of the mass matrix in the form of the Schur Complement is derived as M(exp -1) = C - B(exp *)A(exp -1)B, wherein matrices C, A, and B are block tridiagonal matrices. The new O(n) algorithm is then derived as a recursive implementation of this factorization of M(exp -1). For the closed-chain systems, similar factorizations and O(n) algorithms for computation of Operational Space Mass Matrix lambda and its inverse lambda(exp -1) are also derived. It is shown that these O(n) algorithms are strictly parallel, that is, they are less efficient than other algorithms for serial computation of the problem. But, to our knowledge, they are the only known algorithms that can be parallelized and that lead to both time- and processor-optimal parallel algorithms for the problem, i.e., parallel O(log n) algorithms with O(n) processors. The developed parallel algorithms, in addition to their theoretical significance, are also practical from an implementation point of view due to their simple architectural requirements. Author

PARALLEL METHODS FOR DYNAMIC SIMULATION OF MULTIPLE MANIPULATOR SYSTEMS **c62**
Scott McMillan, P. Sadayappan, and David E. Orin *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 267-281 (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

In this paper, efficient dynamic simulation algorithms for a system of m manipulators, cooperating to manipulate a large load, are developed; their performance, using two possible forms of parallelism on a general-purpose parallel computer, is investigated. One form, temporal parallelism, is obtained with the use of parallel numerical integration methods. A speedup of 3.78 on four processors of CRAY Y-MP8 was achieved with a parallel four-point block predictor-corrector method for the simulation of a four manipulator system. These multi-point methods suffer from reduced accuracy, and when comparing these runs with a serial integration method, the speedup can be as low as 1.83 for simulations with the same accuracy. To regain the performance lost due to accuracy problems, a second form of parallelism is employed. Spatial parallelism allows most of the dynamics of each manipulator chain to be computed simultaneously. Used exclusively in the four processor case, this form of parallelism in conjunction with a serial integration method results in a speedup of 3.1 on four processors over the best serial method. In cases where there are either more processors available or fewer chains in the system, the multi-point parallel integration methods are still advantageous despite the reduced accuracy because both forms of parallelism can then combine to generate more parallel tasks and achieve greater effective speedups. This paper also includes results for these cases. Author (revised)

REAL-TIME DYNAMICS SIMULATION OF THE CASSINI SPACECRAFT USING DARTS. PART 1: FUNCTIONAL CAPABILITIES AND THE SPATIAL ALGEBRA ALGORITHM **c61**
A. Jain and G. K. Man *In its* Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 297-306 (For primary document see N94-14618 02-39)
Avail: CASI HC A02/MF A04

This paper describes the Dynamics Algorithms for Real-Time Simulation (DARTS) real-time hardware-in-the-loop dynamics simulator for the National Aeronautics and Space Administration's Cassini spacecraft. The spacecraft model consists of a central flexible body with a number of articulated rigid-body appendages. The demanding performance requirements from the spacecraft control system require the use of a high fidelity simulator for control system design and testing. The DARTS algorithm provides a new algorithmic and hardware approach to the solution of this hardware-in-the-loop simulation problem. It is based upon the efficient spatial algebra dynamics for flexible multibody systems. A parallel and vectorized version of this algorithm is implemented on a low-cost, multiprocessor computer to meet the simulation timing requirements. Author (revised)

REAL-TIME DYNAMIC SIMULATION OF THE CASSINI SPACECRAFT USING DARTS. PART 2: PARALLEL/VECTORIZED REAL-TIME IMPLEMENTATION **c61**
A. Fijany, J. A. Roberts, A. Jain, and G. K. Man *In its* Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 307-326 (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

Part 1 of this paper presented the requirements for the real-time simulation of Cassini spacecraft along with some discussion of the DARTS algorithm. Here, in Part 2 we discuss the development and implementation of parallel/vectorized DARTS algorithm and architecture for real-time simulation. Development of the fast algorithms and architecture for real-time hardware-in-the-loop simulation of spacecraft dynamics is motivated by the fact that it represents a hard real-time problem, in the sense that the correctness of the simulation depends on both the numerical accuracy and the exact timing of the computation. For a given model fidelity, the computation should be computed within a predefined time period. Further reduction in computation time allows increasing the fidelity of the model (i.e., inclusion of more flexible modes) and the integration routine. Author

A dynamics and controls analyst is typically presented with a structural dynamics model and must perform various input/output tests and design control laws. The required time/frequency simulations need to be done many times as models change and control designs evolve. This paper examines some simple ways that open and closed loop frequency and time domain simulations can be done using the special structure of the system equations usually available. Routines were developed to run under Pro-Matlab in a mixture of the Pro-Matlab interpreter and FORTRAN (using the .mex facility). These routines are often orders of magnitude faster than trying the typical 'brute force' approach of using built-in Pro-Matlab routines such as bode. This makes the analyst's job easier since not only does an individual run take less time, but much larger models can be attacked, often allowing the whole model reduction step to be eliminated. OPTIMIZATION-BASED CONTROLLER DESIGN FOR ROTORCRAFT **c08**
N.-K. Tsing (Maryland Univ., College Park.), M. K. H. Fan (Georgia Inst. of Tech., Atlanta.), J. Barlow (Maryland Univ., College Park.), A. L. Tits (Maryland Univ., College Park.), and M. B. Tischler *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 379-393 (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

An optimization-based methodology for linear control system design is outlined by considering the design of a controller for a UH-60 rotorcraft in hover. A wide range of design specifications is taken into account: internal

stability, decoupling between longitudinal and lateral motions, handling qualities, and rejection of windgusts. These specifications are investigated while taking into account physical limitations in the swashplate displacements and rates of displacement. The methodology crucially relies on user-machine interaction for tradeoff exploration. Author (revised)

ON l(1): OPTIMAL DECENTRALIZED PERFORMANCE c63

Dennis Sourlas and Vasilios Manousiouthakis *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 395-411 (For primary document see N94-14618 02-39)

Avail: CASI HC A03/MF A04

In this paper, the Manousiouthakis parametrization of all decentralized stabilizing controllers is employed in mathematically formulating the l(sup 1) optimal decentralized controller synthesis problem. The resulting optimization problem is infinite dimensional and therefore not directly amenable to computations. It is shown that finite dimensional optimization problems that have value arbitrarily close to the infinite dimensional one can be constructed. Based on this result, an algorithm that solves the l(sup 1) decentralized performance problems is presented. A global optimization approach to the solution of the infinite dimensional approximating problems is also discussed. Author (revised)

A RATIONAL INTERPOLATION METHOD TO COMPUTE FREQUENCY RESPONSE

Charles Kenney, Stephen Stubberud, and Alan J. Laub *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 413-425 (For primary document see N94-14618 02-39)

(Grant AF-AFOSR-0240-91)

Avail: CASI HC A03/MF A04

A rational interpolation method for approximating a frequency response is presented. The method is based on a product formulation of finite differences, thereby avoiding the numerical problems incurred by near-equal-valued subtraction. Also, resonant pole and zero cancellation schemes are developed that increase the accuracy and efficiency of the interpolation method. Selection techniques of interpolation points are also discussed. AN APPLICATION OF THE IMC SOFTWARE TO CONTROLLER DESIGN FOR THE JPL LSCL EXPERIMENT FACILITY c61

Guoming Zhu and Robert E. Skelton *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 427-462 (For primary document see N94-14618 02-39)

Avail: CASI HC A03/MF A04

A software package which Integrates Model reduction and Controller design (The IMC software) is applied to design controllers for the JPL Large Spacecraft Control Laboratory Experiment Facility. Modal Cost Analysis is used for the model reduction, and various Output Covariance Constraints are guaranteed by the controller design. The main motivation is to find the controller with the 'best' performance with respect to output variances. Indeed it is shown that by iterating on the reduced order design model, the controller designed does have better performance than that obtained with the first model reduction. Author

Avail: CASI HC A03/MF A04

The dynamics and control of flexible aerospace structures exercises many of the engineering disciplines. In recent years there has been considerable research in the developing and tailoring of control system design techniques for these structures. This problem involves designing a control system for a multi-input, multi-output (MIMO) system that satisfies various performance criteria, such as vibration suppression, disturbance and noise rejection, attitude control and slewing control. Considerable progress has been made and demonstrated in control system design techniques for these structures. The key to designing control systems for these structures that meet stringent performance requirements is an accurate model. It has become apparent that theoretically and finite-element generated models do not provide the needed accuracy; almost all successful demonstrations of control system design techniques have involved using test results for fine-tuning a model or for extracting a model using system ID techniques. This paper describes past and ongoing efforts at Ohio University and NASA MSFC to design controllers using 'data models.' The basic philosophy of this approach is to start with a stabilizing controller and frequency response data that describes the plant; then, iteratively vary the free parameters of the controller so that performance measures become closer to satisfying design specifications. The frequency response data can be either experimentally derived or analytically derived. One 'design-with-data' algorithm presented in this paper is called the Compensator Improvement Program (CIP). The current CIP designs controllers for MIMO systems so that classical gain, phase, and attenuation margins are achieved. The center-piece of the CIP algorithm is the constraint improvement technique which is used to calculate a parameter change vector that guarantees an improvement in all unsatisfied, feasible performance metrics from iteration to iteration. The paper also presents a recently demonstrated CIP-type algorithm, called the Model and Data Oriented Computer-Aided Design System (MADCADS), developed for achieving H(sub infinity) type design specifications using data models. Control system design for the NASA/MSFC Single Structure Control Facility are demonstrated for both CIP and MADCADS. Advantages of design-with-data algorithms over techniques that require analytical plant models are also presented. Author (revised)

COMPUTATIONAL ISSUES IN OPTIMAL TUNING AND PLACEMENT OF PASSIVE DAMPERS

C. C. Chu and M. H. Milman *In its* Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 479-490 (For primary document see N94-14618 02-39)

Avail: CASI HC A03/MF A04

The effectiveness of viscous elements in introducing damping in a structure is a function of several variables including their number, their location in the structure, and their physical properties. In this paper, the optimal damper placement and tuning problem is posed to optimize these variables. Both discrete and continuous optimization problems are formulated and solved corresponding, respectively, to the problems of placement of passive elements and to the tuning of their parameters. The paper particularly emphasizes the critical computational issues resulting from the optimization formulations. Numerical results involving a lightly damped testbed structure are presented. A Workstation has been designed and constructed for rapidly simulating motions of rigid and elastic multibody systems. We examine the Workstation from the point of view of analysts who use the machine in an industrial setting. Two aspects of the device distinguish it from other simulation programs. First, one uses a series of windows and menus on a computer terminal, together with a keyboard and mouse, to provide a mathematical and geometrical description of the system under consideration. The second hallmark is a facility for animating simulation results. An assessment of the amount of effort required to numerically describe a system to the Workstation is made by comparing the process to that used with other multibody

software. The apparatus for displaying results as a motion picture is critiqued as well. In an effort to establish confidence in the algorithms that derive, encode, and solve equations of motion, simulation results from the Workstation are compared to answers obtained with other multibody programs. Our study includes measurements of computational speed.

CONTROL STRUCTURAL INTERACTION TESTBED: A MODEL FOR MULTIPLE FLEXIBLE BODY VERIFICATION **c18**
M. A. Chory, A. L. Cohen, R. A. Manning, M. L. Narigon, and V. A. Spector *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 507-524 (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

Conventional end-to-end ground tests for verification of control system performance become increasingly complicated with the development of large, multiple flexible body spacecraft structures. The expense of accurately reproducing the on-orbit dynamic environment and the attendant difficulties in reducing and accounting for ground test effects limits the value of these tests. TRW has developed a building block approach whereby a combination of analysis, simulation, and test has replaced end-to-end performance verification by ground test. Tests are performed at the component, subsystem, and system level on engineering testbeds. These tests are aimed at authenticating models to be used in end-to-end performance verification simulations: component and subassembly engineering tests and analyses establish models and critical parameters, unit level engineering and acceptance tests refine models, and subsystem level tests confirm the models' overall behavior. The Precision Control of Agile Spacecraft (PCAS) project has developed a control structural interaction testbed with a multibody flexible structure to investigate new methods of precision control. This testbed is a model for TRW's approach to verifying control system performance. This approach has several advantages: (1) no allocation for test measurement errors is required, increasing flight hardware design allocations; (2) the approach permits greater latitude in investigating off-nominal conditions and parametric sensitivities; and (3) the simulation approach is cost effective, because the investment is in understanding the root behavior of the flight hardware and not in the ground test equipment and environment. DESIGN AND CONTROL OF A MACRO-MICRO ROBOT FOR PRECISE FORCE APPLICATIONS **c63**
Yulun Wang, Amante Mangaser, Keith Laby, Steve Jordan, and Jeff Wilson *In* JPL, Proceedings of the Fifth NASA/NSF/DOD Workshop on Aerospace Computational Control 15 Feb. 1993 p 535-552 Sponsored in part by NSF (For primary document see N94-14618 02-39)
Avail: CASI HC A03/MF A04

Creating a robot which can delicately interact with its environment has been the goal of much research. Primarily two difficulties have made this goal hard to attain. The execution of control strategies which enable precise force manipulations are difficult to implement in real time because such algorithms have been too computationally complex for available controllers. Also, a robot mechanism which can quickly and precisely execute a force command is difficult to design. Actuation joints must be sufficiently stiff, frictionless, and lightweight so that desired torques can be accurately applied. This paper describes a robotic system which is capable of delicate manipulations. A modular high-performance multiprocessor control system was designed to provide sufficient compute power for executing advanced control methods. An 8 degree of freedom macro-micro mechanism was constructed to enable accurate tip forces. Control algorithms based on the impedance control method were derived, coded, and load balanced for maximum execution speed on the multiprocessor system. Delicate force tasks such as polishing, finishing, cleaning, and deburring, are the target applications of the robot. Author

The Multibody Modeling, Verification, and Control (MMVC) Laboratory is under development at NASA MSFC in Huntsville, Alabama. The laboratory will provide a facility in which dynamic tests and analyses of multibody flexible structures representative of future space systems can be conducted. The purpose of the tests are to acquire dynamic measurements of the flexible structures undergoing large angle motions and use the data to validate the multibody modeling code, TREETOPS, developed under sponsorship of NASA. Advanced control systems design and system identification methodologies will also be implemented in the MMVC laboratory. This paper describes the ground test facility, the real-time control system, and the experiments. A top-level description of the TREETOPS code is also included along with the validation plan for the MMVC program. Dynamic test results from component testing are also presented and discussed. A detailed discussion of the test articles, which manifest the properties of large flexible space structures, is included along with a discussion of the various candidate control methodologies to be applied in the laboratory. EFFECT OF SIZE, SHAPE, AND END CONDITION OF TEST SPECIMEN ON COMPRESSIVE STRENGTH OF HIGH-STRENGTH CONCRETE
A. Ipatti 1992 50 p
(DE93-500412; IVO-A-10/92) Avail: CASI HC A03/MF A01

Compressive testing of high-strength concrete is a critical issue on which no consensus has yet been reached. Among the many factors that are under discussion are the size, shape, and end condition of test specimens for high-strength concrete. The experimental program described herein was designed primarily to investigate the effects and the possible interactions of the above-mentioned factors on compressive strength of high-strength concrete. Three levels of specimen sizes, three methods of specimen capping (mould surface, sulphur capping, grinding), and four grades of concrete strengths were selected. A 3 x 3 x 4 factorial experimental design was adopted with two replicates (each an average of three specimens), giving a total of 72 test values (216 specimens). The strictest possible precautions were taken to ensure that all other factors which would conceivably effect the compressive strength were held constant. The statistical methods utilized included analyses of variance, linear regressions, and pairwise comparisons of factor main effects. DOE

The development of the Delft Interactive Shell Design Code (DISDECO) is described. The purpose is to make the accumulated theoretical, numerical, and practical knowledge of the last years readily accessible to users interested in the analysis of buckling sensitive structures. With this open ended, hierarchical, interactive computer code, the user can access

workstation programs of increasing complexity. As a first update of DISDECO, the computational modules of the initial level were modified so as to handle combined loads consisting of axial compression, internal and external pressure, and clockwise or counter clockwise torque. The applied load is assumed to have a uniform spatial distribution and is divided into a fixed and a variable part. The magnitude of the variable part is allowed to vary in proportion to a load parameter Lambda. This leads to an eigenvalue problem for the critical lambda sub C. ESA

BUCKLING ANALYSIS OF LAMINATED THIN SHELLS IN A HOT ENVIRONMENT
Pascal K. Gotsis and James D. Guptil Sep. 1993 22 p
(RTOP 537-04-20)
(NASA-TM-106302; E-8043; NAS 1.15:106302) Avail: CASI HC A03/MF A01

Results are presented of parametric studies to assess the effects of various parameters on the buckling behavior of angle-ply, laminated thin shells in a hot environment. These results were obtained by using a three-dimensional finite element analysis. An angle-ply, laminated thin shell with fiber orientation of (theta/-theta)(sub 2) was subjected to compressive mechanical loads. The laminated thin shell had a cylindrical geometry. The laminate contained T300 graphite fibers embedded in an intermediate-modulus, high-strength (IMHS) matrix. The fiber volume fraction was 55 percent and the moisture content was 2 percent. The residual stresses induced into the laminate structure during the curing were taken into account. Parametric studies were performed to examine the effect on the critical buckling load of the following parameters: cylinder length and thickness, internal hydrostatic pressure, different ply thicknesses, different temperature profiles through the thickness of the structure, and different lay up configurations and fiber volume fractions. In conjunction with these parameters the ply orientation was varied from 0 deg to 90 deg. Seven ply angles were examined: 0 deg, 15 deg, 30 deg, 45 deg, 60 deg, 75 deg, and 90 deg. The results show that the ply angle theta and the laminate thickness had significant effects on the critical buckling load. The fiber volume fraction, the fiber orientations, and the internal hydrostatic pressure had important effects on the critical buckling load. The cylinder length had a moderate influence on the buckling load. The thin shell with (theta/-theta)(sub 2) or (theta/-theta)(sub s) angle-ply laminate had better buckling-load performance than the thin shell with (theta)(sub 4) angle-ply laminate. The temperature profiles through the laminate thickness and various laminates with the different ply thicknesses has insignificant effects on the buckling behavior of the thin shells. A COMPUTER PROGRAM TO CALCULATE GROWTH RATES FOR CRACKS AT NOTCHES IN REGIONS OF RESIDUAL STRESS
R. Cook, S. Dorey, and D. P. Rooke 24 Nov. 1992 57 p
(RAE-TM-Mat/Str-1207; ICAF-1866; BR316512; ETN-93-94501) Copyright Avail: CASI HC A04/MF A01

A computer program which can be used to predict the growth rates of fatigue cracks emanating from notches and growing through residual stress fields is described. The residual stress distributions, alternating loading conditions and specimen geometry must be specified by the user. The program uses a Green's function technique to calculate the stress intensity factor due to the applied and residual stresses for any crack length. The calculated stress intensity factor can be corrected to account for the exact crack shape, if it is known. The crack growth rate is obtained from a data base of experimentally determined crack growth data as a function of stress intensity factor, for a number of different materials. ESA

NONLINEAR WAVE FORCES ON LARGE OCEAN STRUCTURES Final Report, Oct. 1991 - Sep. 1992
Erick T. Huang Apr. 1993 53 p
(DA Proj. R00-0-NO)
(AD-A266820; NCEL-TN-1857) Avail: CASI HC A04/MF A01

This study explores the significance of second-order wave excitations on a large pontoon and tests the feasibility of reducing a nonlinear free surface problem by perturbation expansions. A simulation model has been developed based on the perturbation expansion technique to estimate the wave forces. The model uses a versatile finite element procedure for the solution of the reduced linear boundary value problems. This procedure achieves a fair compromise between computation costs and physical details by using a combination of 2D and 3D elements. A simple hydraulic model test was conducted to observe the wave forces imposed on a rectangle box by Cnoidal waves in shallow water. The test measurements are consistent with the numerical predictions by the simulation model. This result shows favorable support to the perturbation approach for estimating the nonlinear wave forces on shallow draft vessels. However, more sophisticated model tests are required for a full justification. Both theoretical and experimental results show profound second-order forces that could substantially impact the design of ocean facilities. DTIC

INTEGRATION OF SPACE AND IN-SITU OBSERVATIONS TO STUDY ATMOSPHERE, OCEAN AND LAND PROCESSES Final Technical Report, 1 Sep. 1987 - 31 Aug. 1992
J. Shukla and J. L. Kinter, III 1992 11 p
(Grant NAGw-1166)
(NASA-CR-194495; NAS 1.26:194495) Avail: CASI HC A03/MF A01

A research investigation was conducted into the possibility of using atmospheric observations made in the past from both terrestrial and space-based platforms to create a global, coherent four dimensional analysis for the purpose of studying atmospheric, oceanic, and land surface processes relevant to climate simulation, monitoring, and change. This investigation consisted of the following tasks: (1) a mature global data assimilation system was obtained from the National Meteorological Center and modified for use on a Cray X-MP computer system; (2) atmospheric observations for the period 20 Nov. 1982 through 1 Mar. 1983, including rawinsonde soundings, aircraft-based measurements, pilot balloons, and temperature soundings from polar orbiting satellites were obtained from several sources; and (3) the global data assimilation system was used to reassimilate the atmospheric observations to produce a new atmospheric analysis which was then compared with the contemporaneous analysis. The global hydrologic cycle, including fluxes between the atmosphere and both the land and ocean surfaces, was estimated. The flux of water from the ocean surface into the atmosphere, its transport in the form of latent heat to remote regions, and its return to the surface in the form of precipitation were estimated globally. In addition, several regional budgets for selected tropical oceanic and extratropical continental areas were also done.

DENDROMETRIC VARIABLES ESTIMATION IN HOMOGENEOUS FORESTS USING LANDSAT TM DATA M.S. Thesis, 1991 [ESTIMATIVA DE VARIAVEIS DENDROMETRICAS EM FLORESTAS HOMOGENEAS A PARTIR DE DADOS LANDSAT TM]
Marcos Leandro Kazmierczak Jan. 1992 211 p In PORTUGESE Original contains color illustrations
(INPE-5455-TDI/497) Avail: CASI HC A10/MF A03

The obtainment of information inherent to growing and productivity is fundamental for forest activities planning, due to the long periods of time involved between implementation and final cut. Considering the fact that the obtainment of this information through traditional forest inventory represents a very high cost, a methodology associating field and orbital data was developed to generate prognosis equations. The study area defined for this work was the Passo Fundo National Forest (RS), in areas with 'Araucaria angustifolia' and 'Pinus.' The inventory of natural sites regarding types of soil rended as a base for the forest inventory, supplying stratified information, which were then correlated with orbital data. The approach applied presented some promising results on the estimate of general dendrometric variables from spectral data measured by the TM (Thematic Mapper) sensor, on board the Landsat-5 satellite. The quadratic function (Y = a+bX+cX(exp 2)) seemed the function that best adjusts the data into two studied species and the TM5 spectral response (1.55 to 1.75 m) seemed the isolated band to constitute the best independent variable. The quantification of some variables of interest could be done within acceptable error levels, as in the case of basal area in Pinus (8.16 percent). The dominant height and the basal area variables for Araucaria and the annual medium increment in volume, medium height, basal area and age for Pinus could be estimated with an accuracy between 84 and 92 percent, allowing the obtainment of preliminary information more rapidly and with lower costs. EVALUATION OF BETA-SPLINE INTERPOLATION IN DIGITAL TERRAIN MODELS Thesis [AVALIACAO DO INTERPOLADAR BETA-SPLINE EM MODELOS DIGITAIS DE ELEVACAO]
Carlos Eduardo Nery Jun. 1992 68 p In PORTUGESE
(INPE-5475-TDI/506) Avail: CASI HC A04/MF A01

The objective is to study the beta-Spline interpolator and evaluate its capability to generate Digitals Elevation Models. The study area is localized in the periphery of the city of Belo Horizonte, the principal district of the state of Minas Gerais. This place was chosen because it had digital format datas, and this made the ground survey more simple. In the beginning, the software was developed in PC computers but then it was necessary to work with VAX computer. Then two kinds of languages were used: C language (for PC's) and FORTRAN languages (for VAX). The results were evaluated applying the STATGRAPHICS software, and are graphically presented to be possible a visual analysis between the real model and the interpolated model generating a difference model. J2000.0 MODELLING OF GEOAIM IN THE ANALYSIS OF VLBI DATA FROM THE NASA CRUSTAL DYNAMICS PROJECT M.S. Thesis
Xin Tan Jul. 1990 167 p
(ISBN-0-315-59463-2; CTN-93-60857) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

GEOAIM (GEOdetic Analysis of Interferometric Measurements) is a very long baseline interferometry (VLBI) data analysis program created in 1979 and updated several times since. The latest revision, called GEOAIM-2000, was developed to replace the old time reference epoch B1950.0 definitions and constants with the ones of J2000.0. Sixteen subprograms in the software package were amended and some other options were added to make GEOAIM-2000 more flexible in the analysis of VLBI data sets. A new ionospheric correction program was developed to enable freeing of data from ionospheric delay before GEOAIM-2000 processing. Some results are presented from using GEOAIM-2000 to process eight data sets collected under NASA's Crustal Dynamics Project 1984-85 at seven VLBI stations in North America. The processing results of six baselines and the positions of seven stations from GEOAIM-2000 processing indicate that cm-level repeatability in baseline length and tens of cm level repeatability in the relative position of stations was achieved. Comparison of the precession results from GEOAIM-2000 and its previous version shows that the accuracy of the model was increased by more than two orders of magnitude. Comparison of these results with those from NASA Goddard Space Flight Center show a few tens of cm of difference in values. Author (CISTI)

Comprehension of the spectral reflectance of soils is required for effective use of remote sensing products. The absence of studies concerned to spectral reflectance of the soils from the tropical region in the 400 to 2500 nm spectral range is the main motivation of this research. The aim is the obtention of the bidirectional reflectance factor of 111 selected soil samples, grouped in 14 soil classes, taken from 54 sites (Sao Paulo State, Brazil). Each soil sample is associated to a set of physical and chemical analyses data. Part of these sites are characterized in published descriptive reports on soil surveys. The dependence between these and the spectral data were discussed. IRIS spectroradiometer, which can operate in the 400 to 2500 nm region of the electromagnetic spectrum, was used for the bidirectional reflectance factor measurements. It was also made a colorimetric analysis, which resulted in bright and saturation values, as well as in the dominant wavelength and in the tricromacity coordinates of the soil samples colors. Besides the analyses of the physical and chemical properties, a trial about moisture effects on the reflectance of selected soil samples was conducted. Additionally, colored photographs of samples are presented to allow observation of their superficial conditions. Author

A method for mapping the spatial distribution of surface net radiation in mountainous terrain using Landsat 5 Thematic Mapper (TM) imagery and digital terrain data is presented. Digital terrain data were used for image registration, atmospheric corrections in satellite imagery, and together with a two-stream radiation transfer model for the computation of shortwave and longwave irradiance. The visible, near infrared and mid-infrared reflectance derived from Landsat TM were combined into a measure of albedo using a weighted average scheme. Landsat TM thermal Band 6 was utilized in the determination of surface thermal excitance. Predicted values of shortwave and longwave irradiance, as well as of surface albedo and thermal excitance, were evaluated against field measurements. The proposed method using Landsat-5 TM imagery and digital terrain data yielded data in good agreement with data obtained using traditional field instruments. Maps of surface albedo, thermal excitance, and net radiation were produced to examine the spatial distribution of these parameters along a transect in the Colorado Front Range. Implications of this work for the modeling of daily net shortwave radiation in the alpine tundra are discussed. Diurnal variations of net shortwave radiation for selected cover types in the study area are summarized in graphical form. Author (CISTI)

A KNOWLEDGE-BASED MODEL FOR THE INTEGRATION OF REMOTE SENSING INTO A MINERAL EXPLORATION PROGRAM Ph.D. Thesis
John Keith Hornsby Apr. 1990 328 p
(ISBN-0-315-58982-5; CTN-93-60730) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

A study was conducted to research, develop, and demonstrate a knowledge based model for the application of remote sensing to mineral exploration in the Canadian environment. This environment is characterized by the cover of vegetation and various depths of overburden separating the bedrock geology of interest from the sensor. The study area chosen to test the model is situated in the Grenville province in Ontario, where exploration and mining activities have taken place for Au, Pb, and Zn associated with metavolcanics and overlying carbonates. The remote sensing exploration model is hierarchical, progressing through reconnaissance and detailed exploration levels with associated stages to achieve the goal of targeting sites of high mineral potential. The model focuses on obtaining evidence to support a working model of mineralization. The strategic approach developed is based on the concept of geobotany, in that vegetation will reflect in some degree the underlying geology. A methodology has been developed to identify anomalous areas in the remote sensing data using a geobotanical strategy. Data processing procedures were determined and geobotanical relationships identified. A methodology was developed to integrate geophysical, geobotanical, and geochemnical anomalies to produce mineral potential maps. Author (CISTI)

APPLICATION OF TRANSIENT AIRBORNE ELECTROMAGNETIC AND GROUND RESISTIVITY METHODS TO GEOLOGICAL MAPPING IN TROPICAL TERRAINS Ph.D. Thesis
Justus Obiko Barongo May 1989 228 p
(ISBN-0-315-57172-1; CTN-93-60727) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

The feasibility of using ground resistivity and time domain airborne electromagnetic (AEM) methods in geological mapping in tropical terrains is investigated. The investigation is based on evaluation of the linear inverse theory in the determination of physical parameters of the weathered layer necessary for interpretation of underlying lithology. Inversion of ground resistivity sounding data from the greenstone belt in western Kenya yields conductivities and thicknesses consistent with geology. A similar inversion of modelled time domain airborne electromagnetic data shows that conductivity, thickness, and depth to the top of the conductive weathered layer can be uniquely determined if its response does not suffer the thin sheet response problem. The results further show that this problem can be quite common in tropical regions since much of the weathered layer has low conductivity and thickness and, consequently, the response is weak. In this situation, conductivity and thickness are correlated and conductivity thickness product is better determined than these two parameters independently. By virtue of the weak time domain AEM response of the weathered layer, much of the response remains buried in noise. A method for reducing some of this noise before carrying out the inversion is presented. Author (CISTI)

ANALYTICAL FRAMEWORK FOR MODELING SCALE-RELATED VARIABILITIES IN REMOTE SENSING Ph.D. Thesis
Chaur-Fong Chen 1992 126 p
Avail. Univ. Microfilms Order No. DA9311051

A general analytical framework was established to investigate the scale-related variabilities in remote sensing. The variabilities were studied first by investigating canopy structure, canopy interaction with light, relation between spectral reflectance and plant phenological parameters. The variabilities simulated by the plant model were compared with the actual spectral data acquired by ground spectroradiometer and satellite sensors. The theoretical relation between orthogonal based transform and Kahunen-Loeve transform was investigated in the vector space. The role of spectral indices in identifying the status of phenological parameters was briefly studied. The radio metric corrections of the remotely sensed data were carefully controlled to avoid the unwanted noise introduced by typical resampling/correction procedures from commercial operation. The nonlinearity and sensor response corrections were applied to the spectral data as necessary. Variability analysis was conducted to illustrate the complexities of spectral variability embedded in the remotely sensed data. The information extraction in spatial frequency domain was investigated with emphasis in Fourier domain feature extraction. The Radon transform was introduced as the potential tool to enhance the spatial information of the Fourier transformed image. The adequacy of entropy and fractal dimension as image information measures was proved. A functional link between entropy and fractal dimension was established. The image information content was extracted using various first and second order statistics, entropy, and fractal dimension. Results were presented for different remote sensors based on the full image information content and specific agricultural ground features. The quality of spatial resampling algorithms was tested by investigating the capability to maintain image information in the resampled image. Finally, two applications utilizing this analytical framework were presented to show its potential in land-use classification and multiscale data fusion. Dissert. Abstr.

The nature of the spectral interaction between radiant energy and the Earth's surface components is very important for the development of Remote Sensing techniques. One of the most effective ways to understand those interactions is through the measurement and analysis of the spectral reflectance of those components. The use of field ground reflectance data for the calibration of satellite imagery can be more accurate if the measurements are done using a radiometer whose field of view has similar dimensions to that of the satellite imaging system. Many modern spectral radiometers, based upon CCD technology, have made the field reflectance measurements easier owing to their portability, speed of data acquisition and reliability. To take advantage of these new capabilities and to fulfill the geometric and spectral requirements of the ground data, the Laboratory for Radiometry of the National Institute of Space Research (INPE/BRAZIL),

developed the Airborne Data Acquisition System (SADA), that uses two SPECTRON SE590 radiometers and an helicopter as its operational platform. The SADA system is able to collect ground reflectance spectra at high sampling rates and over extensive or inaccessible targets such as water bodies and forests. The first operational test of the system was carried out on the Barra Bonita reservoir at the Sao Paulo State. In this experiment the SADA was used for the measurement of the bidirectional spectral reflectance factors of the different water masses of the reservoir. The results of this test showed that the system has an excellent operational flight performance and is very effective for the quick collection of field reflectance data over this kind of target. SATELLITE IMAGERY AND EXOGENOUS DATA INTEGRATION BY NEURAL NETWORK IN AUTOMATION LAND-COVER CLASSIFICATION
Maria Suelena S. Barros 1993 10 p Presented at the International Society for Optical Engineering - SPIE, Washington, DC, Jul. 1992
(INPE-5480-PRE/1778) Avail: CASI HC A02/MF A01

Certainly data integration for land-cover classification requires a non-linear system to associate satellite imagery with exogenous imagery. In this study we present some results of a Neural Network based methodology to provide land-cover classifications. Two approaches are investigated: (1) The Monolithic integration: all required registered images are the inputs of only one Back-Error Propagation (BEP) network. The network is trained on purpose to get the final classification. (2) The class-distributed integration: for each class a specific network learns from all satellite imageries its class characteristics. In both approaches, topographic mapping is taken into account as exogenous data. Author (revised)

NONLINEAR ASPECTS OF DATA INTEGRATION FOR LAND-COVER CLASSIFICATION IN A NEURAL NETWORK ENVIRONMENT
Maria Suelena S. Barros and Valter Rodrigues 1993 17 p Presented at the 29th Plenary Meeting of the Committee on Space Research - COSPAR/The World Congress, Washington, DC, 1992
(INPE-5479-PRE/1778) Avail: CASI HC A03/MF A01

Some results of exploring nonlinear aspects of a neural network methodology to provide land-cover in satellite imagery are presented. All required images are used in a Back-Error Propagation (BEP) network which is a nonlinear data integrator for spatial patterns classification. The network is trained to give the basic categories: grass, moisted soil, bare soil, forest, water and built-up areas. The results of a partial classification are used in a posterior analysis which is done to get the final classification in more detailed classes of land use. The performance results show how powerful a neural-network based methodology is for satellite imagery integration and classification. Author (revised)

THEORY OF POST-BLOCK 2 VLBI OBSERVABLE EXTRACTION
Stephen T. Lowe 15 Jul. 1992 131 p
(NASA-CR-194543; JPL-Publ-92-7; NAS 1.26:194543) Avail: CASI HC A07/MF A02

The algorithms used in the post-Block II fringe-fitting software called 'Fit' are described. The steps needed to derive the very long baseline interferometry (VLBI) charged-particle corrected group delay, phase delay rate, and phase delay (the latter without resolving cycle ambiguities) are presented beginning with the set of complex fringe phasors as a function of observation frequency and time. The set of complex phasors is obtained from the JPL/CIT Block II correlator. The output of Fit is the set of charged-particle corrected observables (along with ancillary information) in a form amenable to the software program 'Modest.' Author (revised)

In this paper we investigate the applicability of the feature extraction mechanisms found in the neurophysiology of mammals to the problem of object recognition in synthetic aperture radar imagery. Our approach is to present multiple views of objects to be recognized to a two-stage self-organizing neural network architecture. The first stage, a two-layer Neocognitron, performs feature extraction in each layer. The resulting feature vectors are presented to the second stage, an ART-2A classifier, self-organizing neural network which clusters the features into multiple object categories. The feature extraction operators resulting from the self-organization process are compared to the feature extraction mechanisms found in the neurophysiology of vision. In a previous paper, the Neocognitron was trained on raw SAR imagery. The architecture was able to recognize a simulated vehicle at arbitrary azimuthal orientations at a single depression angle while rejecting clutter as well as other vehicles. Feature extraction on raw imagery yielded features that were robust but very difficult to interpret. In this paper we report the results of some new experiments in which the self-organization process is applied separately to shadow and bright returns from objects to be recognized. Feature extraction on shadow returns yield oriented contrast edge operators suggestive of bipartite simple cells observed in the striate cortex of mammals. Feature extraction on the specularity patterns in bright returns yield a collection of operators resembling a two-dimensional Haar basis set. We compare the performance of the earlier two-stage neural network trained on raw imagery with a modified network using the new feature set. DOE

Remote sensing techniques were used for meteorological and oceanographic studies, mainly based on satellite data. Aerial multiband SAR (Synthetic Aperture Radar) techniques were used for sea bottom mapping. Satellite observations were combined with in situ measurements and a temperature model for a three dimensional temperature field of seas. Remote sensing techniques were used for the operational management and morphodynamic studies of the Wadden sea. Satellite data were used to establish land use data bases. Tropospheric trace gases were analyzed in the framework of climatological and environmental studies. Meteosat measurements were used to establish mesoscale energy balances of Egypt and Bostwana. Several technological developments were performed. ESA

OPTICAL PROPERTIES OF CO2 ICE AND CO2 SNOW IN THE ULTRAVIOLET, VISIBLE, AND INFRARED Final Report, 1 Jun. 1989 - 30 Nov. 1992
Stephen Warren 31 Aug. 1993 8 p
(Grant NAGw-1734)
(NASA-CR-194110; NAS 1.26:194110) Avail: CASI HC A02/MF A01

The project was to measure the optical constants of CO2 ice in the spectral regions of weak absorption. Many previous measurements had been made by others in the strong absorption bands, but the weak regions had been poorly measured or not measured at all. In these regions the emissivity of CO2 frost and CO2 clouds is quite sensitive to particle sizes

and to the value of the absorption coefficient, so the new measurements will have applications to energy budget and remote sensing of the Martian surface and atmosphere. During the time period covered by this grant, a method was developed for growing clear crystals of CO2, 4 cm in length. An apparatus was constructed for accurate measurement of spectral transmission through these crystals, for wavelengths 0.18-3.8 micrometers, covering the near-ultraviolet, visible, and near-infrared regions, bounded by the strong ultraviolet absorption and the 4.3-micrometer band. Our new best estimate of the spectral absorption coefficient (expressed as imaginary refractive index) is shown. It is a composite result of many measurements on dozens of crystals. Now that we have a good dataset for the shortwave absorption spectrum, the focus of the research has moved to the thermal infrared, for which a Fourier Transform interferometer has been adapted for use with C02-ice crystals. INTELLIGENT ENVIRONMENT FOR INTERPRETATION TASKS OF REMOTELY SENSED IMAGES
Carlos Alberto deOliveira 1993 9 p Presented at the 17th Congress ISPRS, Washington, DC, 2-14 Aug. 1992
(INPE-5466-PRE/1774) Avail: CASI HC A02/MF A01

Digital image interpretation tasks in Remote Sensing applications have been exhaustively studied. Achievements in the area have used deterministic and statistical algorithms. Usually these algorithms only base their decisions on spatial data furnished as representative of patterns (classes). This paper presents a study on the use of Artificial Intelligence (AI) Techniques for interpretation purposes. The following topics are covered in the paper: representation of the knowledge involved in interpretation tasks (local and spatial ones), development or an intelligent interface (for Brazilian users) for interactive classification tasks and educational purposes in Remote Sensing, and the use of the PROLOG language as the principal tool for implementing the inference rules. As a preliminary result a prototype has been tested translating Natural Language queries (in Portuguese) into a Geometric representation language. Author

The objectives of this study were to assess: the possibilities of using cadastral ownership boundaries to extract land cover data from satellite images by means of the object classification; the accuracy of the cadastral land use and remote sensing derived land cover data; and the use of satellite remote sensing for updating the cadastral land use data. For this purpose the digital cadastal boundaries and a Spot and Thematic Mapper image were required for the Lunteren area (The Netherlands). The Lunteren area is a rural area of 3600 ha, consisting of 2110 cadastral parcels. Both satellite images were used for a multitemporal object classification which resulted in one land cover label per cadastral parcel. The underlying assumption of the object classification is that one object (one cadastral parcel) has one land cover type. The multitemporal classification was realized by means of a look up table. The classification results were compared with observations from a field survey in which 289 cadastral parcels were visited. The selection of these parcels was based on a number of criteria to enable comparison between the land use data as stored at the Cadaster (in AKR, an information system that stores administrative information for each cadastral parcel), and the land cover derived from remote sensing. MULTISENSOR REMOTE SENSING DATA AND GIS TECHNIQUES FOR MONITORING PRESERVATION AREAS: A CASE STUDY
Yosio Edemir Shimabukuro, David Chung Liang Lee, and Joao RobertodosSantos Jun. 1991 14 p Presented at the 24th International Symposium on Remote Sensing of Environment, Rio de Janeiro, Brazil, 27-31 May 1991 Previously announced in IAA as A92-41028
(INPE-5317-PRE/1714) Avail: CASI HC A03/MF A01

The objective is to present the capability of remote sensing and GIS techniques for detecting and monitoring the anthropic alterations (mainly, fire action) which sometimes occur in preservation areas. For example, in the Brazil Central region occupied by savanna ('cerrado'), the vegetation burning procedure is commonly employed in the process of implantation and management of cattle raising and agricultural activities. During this annual burning process, fires even reach the environmental protection areas such as National Parks. The Emas National Park, located in South-western of Goias State, Brazil, between 52 deg 40 min W to 53 deg IO min W and 17 deg 50 min S to 18 deg 25 min S, was selected as the study area. This National Park had its area frequently burned in the dry season, as well as in August, 1988. In this investigation, the TM/Landsat data from 29 July 1988 (before the fire) and 14 August 1988 (after the fire) and AVHRR/NOAA data obtained in this period covered by TM images were used for monitoring the biomass burning. The TM images were registered to a topographic map in order to build a database including information such as drainage, roads, elevation and vegetation type for this National Park. Pixels classified as burned areas using band 3 (3.55 um to 3.93 um) of AVHRR images were overlayed on the map derived from the database. The SITIM (Image Processing System) and SGI (Geographic Information System) developed by INPE were utilized in this research. The integration of elevation, TM multitemporal data and information extracted from AVHRR images is a valuable tool for the managers to detect and evaluate the damage occurred as well as to monitor the regeneration process of land cover. AN ALGORITHM FOR THE REMOTE SENSING OF FOG USING SATELLITE-DATA AND ADDITIONAL INFORMATION [EIN ALGORITHMUS ZUR NEBELFERNERKUNDUNG AUS SATELLITENDATEN UND ZUSATZINFORMATIONEN]
Stephan Schaedlich Aug. 1992 85 p In GERMAN
(DLR-FB-92-23; ETN-93-93740) Avail: CASI HC A05/MF A01

The development of an algorithm for the detection of fog during daytime using NOAA-AVHRR (Advanced Very High Resolution Radiometer) data is described. APOLLO programs are applied to perform cloud detection, cloud classification, and cloud analysis using AVHRR data. Both for the development and the verification, additional information is integrated (synopdata, digital elevation model). The fog detection will be carried out in two steps: after the separation of fog or low stratus from other clouds, land, and ocean, an attempt is made to separate fog from low stratus. The statistical verification with synopdata shows that fog and low stratus are well detected only at radiation weather conditions. The described automatic method for the determination of the cloud top heights of fog and low stratus does not work at all times. ESA

OVERVIEW: GAS HYDRATE GEOLOGY AND GEOGRAPHY
R. D. Malone 1993 9 p Presented at the International Conference on Natural Gas Hydrates, New Paltz, NY, 20-24 Jun. 1993
(DE93-014043; DOE/METC-C/93/7069; CONF-930687-2) Avail: CASI HC A02/MF A01

Several geological factors which are directly responsible for the presence or absence of gas hydrates have been reviewed. The factors are as follows: tectonic position of the region; sedimentary environments; structural deformation; shale diapirism; hydrocarbon generation and migration; thermal regime in the hydrate formation zone (HFZ); pressure conditions; and hydrocarbon gas supply to the HFZ. Work on gas hydrate formation in the geological environment has made significant advances, but there is still much to be learned. Work is continuing in the deeper offshore areas through the Ocean Drilling Program, Government Agencies, and Industry. The pressure/temperature conditions necessary for formation have been identified for various compositions of natural gas through laboratory investigations, and conditions for formation are being advanced through drilling in areas where gas hydrates exist. With the successful launches and operations of ERS-1 and JERS-1 (Japanese Earth Resources Satellite-1) SAR (Synthetic Aperture Radar), a new era of continuous spaceborne remote sensing of the earth is now open and the synergy provided by the different frequencies of the SAR instruments is fully available. This report summarizes the work performed using ERS-1 data, which started in July 1991 during the ERS-1 commissioning phase and was followed by some additional work performed during the operational phase of the satellite. This work got a natural extension with the experiments we have set up for the JERS-1 system verification program starting in July 1992 and extending to 1993. A preliminary overview of this is presented. Author (NASDA)

GEOLOGIC APPLICATION OF JERS-1 SAR DATA
Yasushi Yamaguchi *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 27-30 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

An overview of the preliminary investigation on the Synthetic Aperture Radar (SAR) images of the Japanese Earth Resources Satellite-1 (JERS-1) mainly for geologic applications is presented. Comparing SAR images acquired by JERS-1 and the ERS-1, the JERS-1 SAR image with a larger off-nadir angle is more useful for geologic interpretation than the ERS-1 SAR image, indicating regional geologic structures such as synclines and anticlines which are important for basic geologic researches and for petroleum exploration. It is concluded that it might be difficult to directly obtain information on rock and soil under tree cover using L-band SAR due to backscattering from vegetation canopy, and the JERS-1 SAR images of L-band exhibit a better capability of discriminating vegetation types, particularly between forests and grasslands than the C-band ERS-1 and X-band airborne SAR images. ARTIFICIAL OIL POLLUTION DETECTION AND WAVE OBSERVATION IN THE SEA ADJACENT TO JAPAN BY ERS-1 SAR
Kenichi Okamoto, Harunobu Masuko, Kenji Nakamura, Masanobu Shimada (National Space Development Agency, Saitama, Japan.), Masao Nakai

(National Space Development Agency, Saitama, Japan.), and Akira Shibata (Meteorological Research Inst., Tsukuba, Japan.) *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 31-34 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

On November 10 and 13, 1991, an experiment was performed to detect an artificial oil pollution and ocean waves by the C-band SAR (Synthetic Aperture Radar) of ERS-1. Artificial oil slick was made by spilling oleyl alcohol from a small vessel in the Pacific Ocean about 100 km off the Coast of Omaezaki, Shizuoka Prefecture, Japan. Sea truth data were gathered from the research vessel 'Keifu-maru' of JMA (Japan Meteorological Agency) and from a small vessel. Synchronous observation by X-band, VV (Vertical Transmission/Vertical Reception Mode) polarization airborne real aperture SLAR (Side-Looking Airborne Radar) of CRL (Communications Research Laboratory) was made together with the observation by SAR. The SAR images were produced by NASDA. In the SAR image, it was found clearly the artificial oil polluted area which looks dark by the damping of the capillary wave on November 10, 1991. The decrement of the scattering cross section was about 2.5 dB at the maximum. Author (NASDA)

AN EXACT PROCESSING ALGORITHM FOR WIDE BEAM SPACEBORNE SAR DATA
Michael Y. Jin *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 35-38 Sponsored by NASA, Washington (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

Signal processing algorithms for a spaceborne SAR (Synthetic Aperture Radar) system were based on the approximation that the phase history of a point-target is a second order polynomial. For a wide beam or a spotlight mode spaceborne SAR systems, this assumption cannot be applied. This report gives the derivation for the spectrum of a wide beam point-target response and describes a processing algorithm based on this spectrum. Author (NASDA)

HIGH PERFORMANCE MULTI-MODE RADAR ALTIMETER FOR FUTURE SPACEBORNE APPLICATION c19
Yong-Hoon Kim *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 39-44 (For primary document see N94-14209 02-43)
Avail: CASI HC A02/MF A04

The new generation of spaceborne radar altimeter will have to provided with several operating modes in order to cope with the various mission requirements such as land topography mapping in high or moderate resolution, wide swath imaging, and possibly rain rate measurement. A system concept of novel high performance radar altimeter to meet that requirements as well as the land and flight experiment results obtained with the first demonstration prototype are described. The advantages of this type altimeter are high measurement accuracy and flexible for the various operation mode. Author (NASDA)

TRMM SYSTEM OVERVIEW AND STATUS IN THE UNITED STATES
John S. Theon *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 73-75 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

An overview of the mission development status of the Tropical Rainfall Measuring Mission (TRMM) in the U.S. is presented. The mission objectives (including the approach for addressing the problems involved in the mission which were facilitated through ground-based radar data, precipitation data acquired in a variety of field experiments including rain gage networks and satellite observations, and modeling to advance understanding of the rainfall and cloud processes); NASA research announcement of TRMM; algorithm development to incorporate the information available from the multiple sensors on TRMM, including Precipitation Radar (PR) and TRMM Microwave Imager (TMI); and the NASA TRMM Office and its activities are outlined. Two instruments related to the rain measuring objectives of TRMM added at the request of NASA, the Clouds and Earth's Radiant Energy System (CERES), and the Lightning Imaging Sensor (LIS) are also outlined.

TRMM PROJECT IN JAPAN: OVERVIEW AND STATUS
Hideo Takamatsu *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 76-79 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

This report describes the TRMM (Tropical Rainfall Measuring Mission) related activities in Japan. Japan's contributions to the TRMM project include development of PR (Precipitation Radar), launching the satellite into orbit, as well as data processing and distribution. PR is the main sensor of the TRMM and will be the first spaceborne rain radar. Also, TRMM is the first foreign user satellite launched by a Japanese launch vehicle. This requires many works to coordinate the interface between the satellite and H-2 launch vehicle as well as Tanegashima launch facilities. Author (NASDA)

TRMM PRECIPITATION RADAR ALGORITHM **c61**
Kenichi Okamoto *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 84-87 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

The TRMM (Tropical Rainfall Measuring Mission) PR (Precipitation Radar) algorithms have been studied by the TRMM PR team. The radar products are classified and are shown according to the processing levels. The general processing structure suggests a primary division of radar algorithms into either deterministic or statistical techniques. The deterministic methods can be divided into backscattering and attenuation methods. Some candidate rain rate retrieval algorithms are introduced with their merits and demerits. The TRMM standard radar algorithms are also introduced according to the processing levels.

ESTIMATE OF SAMPLING ERRORS OF TRMM RAINFALL OBSERVATION BY USING RADAR-AMeDAS COMPOSITE DATA **c47**
Akimasa Sumi, Riko Oki, and aikan Oki *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 88-91 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

Errors of rainfall estimates due to TRMM (Tropical Rainfall Measuring Mission) satellite is estimated by using radar-AMeDAS (Automated Meteorological Data Acquisition System) composite rainfall data around Japan, which is a radar-rainfall estimate validated by dense surface rain-gauge network (AMeDAS). In this study, sampling errors of a monthly rainfall estimate due to TRMM radar measurement are estimated over the TRMM domain (500 km by 500 km) for two years, and it is concluded that the sampling error around Japan is about 20 percent, which is relatively larger than the previous studies.

MULTIPARAMETER AIRBORNE RAIN RADAR DEVELOPMENT FOR TRMM VALIDATION AND TRMM-FOLLOW-ON STUDY **c47**
Hiroshi Kumagai, Kenichi Okamoto, Kenji Nakamura (Ministry of Posts and Telecommunications, Ibaraki, Japan.), Hiroshi Hanado (Ministry of Posts and Telecommunications, Ibaraki, Japan.), and Hiroaki Horie (Ministry of Posts and Telecommunications, Ibaraki, Japan.) *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 92-95 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

The overall feature of the new multiparameter airborne radar developed in the Communications Research Laboratory (CRL) is to provide the useful data for the TRMM (Tropical Rainfall Measuring Mission) algorithm development during pre-launch period and TRMM validation experiments in the mission period. Both coherent radar system and full polarimetric capability, which are newly installed, will allow the microphysics in the precipitation to be extracted in great detail, which contributes the accurate rain retrieval in TRMM through both the development of algorithms and refined precipitation model. The experiments using these capabilities will provide an opportunity to test candidate techniques for future rain radar missions. The system parameters, the block diagram, and signal to noise ratio per pulse of multiparameter airborne radar are shown.

SPACE MEASUREMENTS FOR DETERMINING THE EARTH'S ENERGY AND WATER CYCLES
James C. Dodge *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 96-99 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

This report describes the increasing number of space data sets which are becoming available from current satellite sensors and which may be used to study the earth's global energy and water cycles. An attempt will be made to point out those aspects of each cycle which can be measured well globally and those components which still have large uncertainties. In the process of explaining the cycles, consideration will be given to the flux data from the Earth Radiation Budget Experiment (ERBE); the cloud observations from the global set of satellites participation in the International Satellite Cloud Climatology Project (ISCCP); the water vapor, precipitation, and cloud liquid water observations from the passive microwave radiometer named the Special Sensor Microwave Imager (SSM/I); and sea-surface temperatures from the Advanced Very High Resolution Radiometer (AVHRR). Some of these data are currently available through NOAA/NESDIS (National Environmental Satellite, Data, and Information Service) and/or NASA Distributed Active Archive Centers (DAAC's) or in CD-ROM data sets. Others will soon be available as part of the on-going NASA/NOAA Pathfinder Data Set Program. The report will conclude with a description of the additional value which will be obtained from the Tropical Rainfall Measuring Mission (TRMM) and Earth Observation Satellite (EOS) data in terms of attempting to understand the global cycles as well as trying to detect significant changes or trends over longer periods. Author (NASDA)

FUTURE TRMM FOLLOW-ON MISSION

Nobuyoshi Fugono (Ministry of Posts and Telecommunications, Tokyo, Japan.) and John S. Theon *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 100-103 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

The basic concept of the TRMM (Tropical Rainfall Measuring Mission) follow-on mission to be developed aiming at its launch in 2000 for the data continuation from TRMM is discussed. The basic instruments and radar are rain radar, microwave radiometer, visible and infrared radiometer, CERES (Clouds and Earth's Radiation Energy System) following those for TRMM, upgraded rain radar, and other new instruments if satellite bus limitations and also time and budget allow. The conceivable instruments for the TRMM follow-on mission are: (1) cloud radar; (2) microwave sounder for water vapor and temperature profiling; (3) water vapor LIDAR (Laser Infrared Radar); and (4) wind LIDAR, but only microwave sounder and cloud lidar may remain due to the tight time schedule. Power consumption and weight of radar and the orbit and concept of radar for TRMM follow-on mission are shown. Author (NASDA)

REMOTE SENSING OF LOW LEVEL CLOUD OPTICAL CHARACTERISTICS

Teruyuki Nakajima and Tadahiro Hayasaka (Tohoku Univ., Sendai, Japan.) *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 107-110 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Remote sensing of cloud microphysics is studied making use of spectral solar reflection data. Statistics of retrieved cloud microphysical quantities is further used to evaluate climatic impact of cloud field change in the course of anthropogenic contamination of atmosphere. Case studies of marine stratocumulus clouds, modulated by ship-emitted Cloud Condensation Nuclei (CCN), and cumulus clouds over Amazon area, modulated by forest fire, showed different response of clouds to CCN injection. This difference comes from the difference in CCN concentration in the ambient atmosphere and drizzle particle concentration in clouds. Author (NASDA)

THE EFFECTS OF ANTHROPOGENIC AEROSOLS ON OPTICAL THICKNESS AND PARTICLE SIZE OF CLOUDS. PART 1: RETRIEVAL ALGORITHM **c45**

Zhao Fengsheng and Teruyuki Nakajima *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 111-116 (For primary document see N94-14209 02-43)

Avail: CASI HC A02/MF A04

The radiative calculation and its application of the effects of anthropogenic aerosols on optical thickness and particle size of clouds are outlined. An algorithm for retrieval of the optical thickness and microphysics of aerosol clouds from the AVHRR (Advanced Very High Resolution Radiometer) image was developed. Application of this algorithm to the area nearby the Chinese east coast shows that the results of retrieved optical thickness and microphysics of aerosols and clouds are quite reasonable. Sensitivity to optical thickness and exponent of Junge size distribution, contour of the standard deviation, and example of retrieved cloud optical thickness, effective radius, and geometric standard deviation are shown. Author (NASDA)

CLIMATE PRODUCTS FROM NOAA OPERATIONAL SATELLITES **c47**

P. Krishna Rao and A. Gruber *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 117-120 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Significance of space-based observation in observing and understanding the nature of climate and global change is discussed. Although the current satellites are primarily designed for weather observation, the satellite measurements contain considerable information on climate and global change parameters. Information is available on sea surface temperature, sea ice, vegetation index, planetary radiation budget, clouds, ozone, aerosols, snow cover, and surface temperature. Examples of satellite derived products are as follows: (1) total cloud amount derived from operational geostationary satellites; (2) average snow cover over the Northern Hemisphere obtained from the NOAA polar orbiter satellite visible channel data; (3) the influence of the Mt. Pinatubo aerosols obtained by comparing satellite derived Sea Surface Temperature (SST) anomaly distribution with the ship data; (4) total ozone distribution over the South Pole; and (5) the total ozone amount over the Southern Hemisphere. Author (NASDA)

THE DEVELOPMENT AND IMPLEMENTATION OF AN INTERACTIVE RETRIEVAL/ANALYSIS/FORECAST ALGORITHM **c61**

Henry E. Fleming, Mitchell D. Goldberg, Wayman E. Baker, John C. Derber, and Bert B. Katz (General Sciences Corp., Washington, DC.) *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 130-133 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

A new retrieval system for deriving temperature and moisture profiles from TIROS-N TOVS (TIROS Operational Vertical Sounder) measurements has been developed. This system, unlike the current operational library search approach, uses the six-hour forecast from the NMC (National Meteorological Center's) Medium Range Forecast Model for constructing the retrieval algorithm's initial (first) guess. The system is interactive because the satellite-retrieved parameters, in addition to conventional in situ data, are analyzed to produce initial conditions for the subsequent forecast by NMC's GDAS (Global Data Assimilation System), and that forecast is used as the initial guess for the subsequent temperature/moisture retrievals. The system is expected to become operational as part of NMC's GDAS in 1993. Author (NASDA)

THE REMARKABLE ACHIEVEMENT OF CHINA SATELLITE APPLICATION

Mei-Rong Wu *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 137-140 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

In this report, a brief survey of satellite applications in China is presented. It covers the main fields of satellite application such as telecommunications, earth-observation remote-sensing techniques, meteorological forecasting, and microgravity experiments. A list of 29 launches using home-made satellites and ground equipment can be drawn, including six earth-stationary-orbit communications satellites, 13 low-orbit recoverable remote-sensing satellites, two polar-orbit meteorological satellites, and 12 science-and-technological test satellites. Multiple purpose and typical examples are given showing good social and economic benefits attained. In China, since the successful launch of DFH-1 dated April 24, 1970, 33 launches have been made whereby 33 self-developed satellites, one COMSAT (Communications Satellite Corp., CS) Asia-1, one AUSSAT (Australian Satellite) (CS (Communication Satellite)) and two S & T (Science and Technology) test satellites (one for Pakistan, another for Sweden) were sent into appropriate orbits. SOME POTENTIALS OF THE INDONESIAN REGION FOR EARTH OBSERVATION

J. H. Soenarjo *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 145-148 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

In the effort to increase concern about the planet earth, space science and technology is obviously a good way to benefit mankind. The increasing use of space applications and space research need the support of space technology development, potential locations for earth observation, and international cooperation. Indonesia has been using space technology to sustain national development programs and has been developing infrastructures to carry out space activities. The Indonesian territory lies in the equatorial region which provides some unique atmospheric phenomena, and is abundant of natural resources. Space activities and several international cooperations in Indonesia are described and potential locations of the Indonesian region for earth observation are explained. Author (NASDA)

INTEGRATION OF REMOTE SENSING AND MATHEMATICAL MODELLING IN DISASTER MITIGATION

Mohammad Rezaur Rahman *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 154-157 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Bangladesh is predominantly an agricultural country. Frequently occurring disasters such as floods and cyclones wreak havoc on its agriculture. The disasters can be mitigated considerably if the agricultural plots can be replanted quickly. However, when a disaster strikes, the communication link is usually in disarray and as a result it is often difficult to make a satisfactory estimation of the extent and severity of damage. Moreover, due to the severe limitation of resources, it is usually not possible for the government to cover the entire damaged area. The government needs to make an unpleasant decision regarding which areas to cover and which not to, in order to maximize the return on the agricultural rehabilitation effort. Remote sensing and mathematical modeling can play a useful role in helping decision makers to make timely and sufficiently accurate decisions in this regard. Author (NASDA)

SOIL EROSION MAPPING USING REMOTE SENSING AND GIS TECHNIQUES

Nik Nasruddin Mahmood *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 158-163 (For primary document see N94-14209 02-43)

Avail: CASI HC A02/MF A04

An overview of the soil erosion assessment of land development project areas using remote sensing and GIS (Geographical Information System) techniques, adopting USLE (Universal Soil Loss Equation) of Wischmeiser and Smith with minor modification in estimating some of the relevant parameters, is presented. Both the current soil erosion susceptibility and

the future potential soil erosion susceptibility maps of the Upper King Valley, Selanger, Malaysia, which is currently experiencing dynamic development, were generated and are shown. Author (NASDA)

DETECTING LAND COVER CHANGES IN CHIANG-MAI AREA IN THAILAND

T. Hosomura and P. K. M. M. Pallewatta *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 164-172 (For primary document see N94-14209 02-43)

Avail: CASI HC A02/MF A04

Remote sensing techniques can be effectively used as a tool to monitor land cover change. Global coverage, high spatial resolution, and high revisit capabilities of modern remote sensing satellites provide large amounts of data daily. Land cover changes in Chiang-Mai area in Thailand are analyzed. The study has been carried out using two multitemporal images of MOS-1 (Marine Observation Satellite-1) MESSR (Multispectral Electronic Self-Scanning Radiometer) data. The analysis is done using difference images and classification results. The classification has been carried out using a neural network classifier, whose structure has been obtained by using a special technique developed. Author (NASDA)

LAND EVALUATION FOR AGRICULTURAL PRODUCTIVITY IN NORTH-EAST THAILAND USING LANDSAT TM DATA AND GEOGRAPHIC INFORMATION

Tsuyoshi Akiyama, Genya Saitou, Yasuharu Yamada, Pongpit Piyapongse (Ministry of Agriculture and Cooperatives, Bangkok, Thailand.), and Ekkanit Hansakdi (Ministry of Agriculture and Cooperatives, Bangkok, Thailand.) *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 173-176 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

A method for land use classification suitable for tropical areas with distinct rainy and dry seasons is presented that uses LANDSAT TM (Thematic Mapper) data, geographic information (including soil type and fertilization information), ground truth data, vegetation indices (calculated from the CCT (Computer Compatible Tape) values at TM band 3 and 4), vegetation cover rate, and soil organic matter content derived from the TM band 3 values. The classification results are considered to agree well with the ground truth data, and the trend of land productivity coincided with yield data. The procedure for constructing a productivity map for paddy and upland crop fields is shown. Author (NASDA)

EFFECTS OF TYPHOON ON TOMS DATA **c47**

Nobuo Takeuchi, Fumihiko Hiruma, and Kiyoshi Tsuchiya (Teikyo Univ., Utsunomiya, Japan.) *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 177-180 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Ozone distribution around typhoons in the area bounded by the latitude and longitude lines 18 N/55 N, 105 E/160 E was studied in the typhoon seasons (July to October) during the period 1979 through 1989. Based on the analysis of TOMS (Total Ozone Mapping Spectrometer) data, the signature (pattern of the ozone concentration) is classified as follows: (1) CD (Central Dense)-type--larger ozone concentration in the center surrounded by less concentrated area in the shape of moat around a castle; (2) N-type--similar to CD-type, however, lacking the central part; and (3) S (Spiral)-type--ozone concentration is in the form of spiral converging into the center. Statistical results of the analysis, such as the numbers of ozone signature in the subject study period and tendency or strengthening and weakening the typhoon are outlined. Author (NASDA)

SATELLITE REMOTE SENSING FOR DISASTER MITIGATION

Shinkichi Kishi *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 181-184 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Several examples of detection of the disaster-stricken areas mainly from Landsat data are shown, and based on these examples, a consideration to characterize the future space technological capabilities to the observation monitoring is presented. It has been made clear by the actual examples that the satellite remote sensing will be very useful technology in the operational activities of disaster management in this decade. Resolution and spectral bands of TM (Thematic Mapper) data are actually practical in detection and mapping of the distribution of the regions stricken by the disaster such as flood and volcanic eruption. To realize the administrative use in disaster management of satellite remote sensing, it is necessary to increase the frequency of observation as well as increasing data distribution. Author (NASDA)

A CONCEPT FOR THE WORLD ENVIRONMENT AND DISASTER OBSERVATION SYSTEM

Takaji Kuroda and Shinkichi Koizumi *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 185-188 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

An ideal system to observe the earth's environment and to monitor disaster status using satellites is described. Three possible concepts of a satellite system for continuous and frequent observation of the earth environment and disasters are as follows: (1) a system consisting of geostationary earth observation satellites similar to the current geostationary meteorological satellite system under the World Meteorological Organization; (2) a system based on agreement whereby the countries currently undertaking earth observation; and (3) a completely new international earth observation system. The system configuration of the WEDOS (World Environment Disaster Observation System) and its data-relay-satellite system and ground system composed of MMC (Mission Management Center), SCS (Satellite Control Station), MGS (Master Ground Station), and LUS (Local User Station) are outlined. It can be concluded that the WEDOS system would be an ideal system for a satellite earth observation system on a global scale, and would enable the realization of continuous observation of the earth's environment and disasters. STUDY OF THE CONSEQUENCES OF THE CHERNOBYL ACCIDENT AND TECHNOGENIC ACTIVITY IN THE REPUBLIC BELARUS USING AEROSPACE METHODS **c45**

Alexander Kovalyov *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 189-192 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Maps of radionuclide distribution on the territory of the Republic of Belarus are made using the data of aerial gamma-spectrometry and ground sampling, taking into account radionuclide deposition. The influence of natural and technogenic Potassium-40 on the radiation situation is investigated; a prognosis of radionuclide migration for the next thirty years is made. Using the data of complex aerospace and ground experiments, 12 types of ecological maps of the scale 1:50,000 are made for the districts with intense technogenic stress. Scientific approaches are developed and the first stage of the Belarussian National Ecogeoinformation System is implemented. A helicopter laboratory created in Belarus and equipped with the devices for ultraviolet, visible, infrared, and microwave ranges of spectrum is described, as well as mobile ecological and radiation laboratories. A TENTATIVE PLAN ON CHINA AND ASIAN-PACIFIC SATELLITE SYSTEM FOR DISASTER REDUCTION

Guo-Fu Zhang and Shang-Min Zheng *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 193-198 (For primary document see N94-14209 02-43)

Avail: CASI HC A02/MF A04

China's satellite system for disaster reduction and its implementation, consisting of a space monitoring system of natural disasters and a ground

application system for natural disaster information acquisition and processing is proposed. The main tasks of the system are as follows: (1) to carry out 24 hour, all-weather monitoring of major natural disasters, such as rain storm, flood, drought, forest fire, etc.; (2) to improve the forecast of major natural disasters and the assessment of their effects, thus, providing a scientific basis for decisions on disaster prevention, fighting, and relief works; (3) to assure unimpeded disaster information transmission channels and command channels; (4) to increase capabilities for rapid response to sudden disaster; and (5) to raise the effectiveness of the same. The system would create necessary conditions for China and Asian-Pacific region to participate in international cooperations for utilizing international earth environment and disaster monitoring systems, and for further increasing capabilities of disaster reduction. EARTH OBSERVATION FROM LOW-INCLINATION ORBIT AS A NECESSARY COMPLEMENT TO POLAR MISSIONS

Werner Kirchhof, Dieter Beran, and Torsten Esdar (Dornier System G.m.b.H., Friedrichshafen, Germany.) *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 199-203 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Earth observation on near-polar orbits provides a coverage of nearly the complete globe. By using low-inclination orbits, dominant dynamic processes in the tropics and subtropics can be monitored with high coverage performance. The effects of orbit inclination, altitude and sensor field of view on local observation time, revisit frequency, and illumination conditions are illustrated. These elements describe the capabilities for the measurement of dynamic processes, diurnal cycles, seasonal and interannual variations, and for the forecast or observation of catastrophic events as a necessary complement to polar missions. Time and illumination dependent measurement needs are listed. Author (NASDA)

THE ROLE OF THE DYNAMICS FOR THE DEVIATION OF THE TOTAL OZONE FROM THE LONG-TERM MEAN AT THE EDGE OF THE POLAR VORTEX **c45**

Karin Petzoldt *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 211-214 Sponsored by BMFT (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Dynamic effects causing extremely low ozone columns in winter during 14 years of the TOMS (Total Ozone Mapping Spectrometers) were investigated to separate them from the ozone variations measured during the EASOE (European Arctic Stratospheric Ozone Experiment), the aim of which is to measure chemical tracers responsible for possible ozone destruction at high altitudes. The unusual low ozone columns over Europe during the EASOE winter 1991 and 1992 were generated dynamically by a tropospheric blocking and strong wave activity in the middle stratosphere. The adiabatically cooling produced an elevated tropopause at the edge of the stratospheric vortex over Europe. Ozone was lifted by the adiabatic ascent and transported to higher levels. For all cases of the period 1979 to 92 when TOMS observed total values below 225 DU over Europe, a similar dynamical situation was present with temperatures at the tropopause below -70 C together with 30 hPa temperatures below -82 C.

THE EUROPEAN ARCTIC OZONE EXPERIMENT: AN INVESTIGATION OF NORTHERN HEMISPHERE OZONE DEPLETION **c45**

Richard A. Cox *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 215-219 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Over the past year, new data has been gathered relating to ozone depletion over the Northern Hemisphere. A major contribution to these data has come from the European Arctic Stratospheric Ozone Experiment (EASOE), a campaign built around measurements from aircraft, balloons, and remote sensing from the ground, conducted throughout the winter of 1991/92. This paper provides a description of the activities, a summary of some of the results, and an update on the situation regarding ozone depletion in the Northern Hemisphere. Author (NASDA)

SPACE-BASED ACTIVITIES: SAM 2 AND SAGE 2

Lamont R. Poole *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 220-223 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Long-term stratospheric observations have been made by the orbiting solar occultation instruments, SAM 2 (Stratospheric Aerosol Measurement 2) and SAGE 2 (Stratospheric Aerosol and Gas Experiment 2). SAM 2 (1978-present) has provided 1 km vertical resolution data on aerosol extinction in the polar regions which show the effects of volcanic eruptions on stratospheric aerosol loading as well as the seasonal formation of Polar Stratospheric Clouds (PSC's). SAGE 2 (1984-present) measures ozone, water vapor, and NO2 profiles in addition to multi-wavelength aerosol extinction. These illustrate, for example, seasonal changes in aerosol characteristics and the spatial and vertical extent of the chemically perturbed region over Antarctica in spring. This report describes the two satellite experiments and discusses important results regarding polar stratospheric ozone depletion. Author (NASDA)

NEW EVIDENCES SUPPORTED THE WEI HYPOTHESIS ABOUT THE FORMATION OF THE ANTARCTIC OZONE HOLE **c45**

Ding-Wen Wei *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 224-228 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Based on a great number of data analysis, a new hypothesis on the formation of the Antarctic ozone hole by the end of 1988 has been presented. This is basically an 'electrochemistry-dynamics' model, and it is related to the solar charged particles emission in the 11 year solar cycle and the Antarctic vortex. For short, some scientists call it the Wei hypothesis. In this report, some new evidences such as the trends of upper layer ozone and the Antarctic observations that support it are presented.

MULTI-SOURCE NATIONAL FOREST INVENTORY OF FINLAND

Erkki Tomppo *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 231-235 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

A new forest inventory system developed by the Finnish Forest Research Institute using satellite image data, digital map data, and other geographical data is outlined. Image analysis methods have been chosen so that estimates of all variables of the inventory can be computed for each pixel to produce thematic maps and statistics for large and small areas. The results are compared with the estimate of an in-situ forest inventory and, for large areas, with estimates based on field sample plots of the NFI (National Forest Inventory). The most feasible satellite image data are Landsat TM (Thematic Mapper), SPOT, and MOS-1 (Marine Observation Satellite-1) images. The method of image interpretation and examples of large area results, including possible ways to judge the goodness of estimates by comparing them with those based on field measurements or with characteristics of in-situ inventory data measured for forest management planning purposes are discussed. The utilization of the inventory results is creating new cooperation between practical forestry and forest research.

GLOBAL ASSESSMENT OF HUMAN ACTIVITIES

Yoshiaki Honda and Shunji Murai *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 236-239 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

A world vegetation map has been produced with the use of NOAA GVI (Global Vegetation Index) data. The actual vegetation map shows disturbed or changed land use as a result of human activities. A potential vegetation map through the use of climate data has been produced. This shows the virgin status of vegetation as generated from only climate conditions without disturbances due to human activities. The difference between the actual and potential vegetation tells about the impact of human activities. CO2 fixation change from that difference was estimated. It is of urgent importance to moderate deforestation and to promote reforestation to prevent global warming due to the increase of CO2 in the atmosphere. Therefore, global map for forest conservation/reforestation was generated with the use evaluating land condition such as vegetation and soil. Author (NASDA)

THE SWEDISH ISY CONTRIBUTION

A. Rosenqvist and H. Oesterlund *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 240-243 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

The Swedish contribution in the celebration of the ISY (International Space Year) has materialized in an active participation in the world forest watch project of the earth science and technology panel but also in the training in the remote sensing applications program within the education and applications panel. The Swedish world forest watch contributions have been formed under the theme of remote sensing for forest management. The projects comprise a wide range of forest and forestry remote sensing applications using different technical approaches. Author (NASDA)

N94-14257# Tokyo Univ. (Japan). Inst. of Industrial Science.

VEGETATION MAPPING OF INDO-CHINA PENINSULA USING MOS-1 MESSR AND NOAA AVHRR

Masataka Takagi, Shunji Murai, and Yoshiaki Honda *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 244-247 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

In the Indo-China Peninsula, the ecosystem is changed by commercial logging or shifting cultivation. In order to watch a current environmental condition, a vegetation map of the Indo-China Peninsula is generated using the MOS-1 (Marine Observation Satellite-1) MESSR (Multispectral Electronic Self-Scanning Radiometer) and NOAA AVHRR (Advanced Very High Resolution Radiometer). A total of 405 scenes of MOS-1 MESSR data were selected for the vegetation mapping in order to cover the whole Indo-China Peninsula. These images were synthesized to generate a mosaic image. Most scenes of MOS-1 data were received in different seasons. Therefore, a radiometric correction system for the mosaic image was developed by using a cloud-free mosaic of NOAA AVHRR data with a wide coverage and multitemporal data. This system was very helpful in applying high resolution satellite data to a wide area. A vegetation map was generated from the radiometrically corrected mosaic images with NVI (Normalized Vegetation Index) value. Vegetation distributions of four countries (Thailand, Cambodia, Laos, Vietnam) were compared with land use data made by the FAO (Food and Agriculture Organization). In Cambodia, the vegetation area is much less than the statistics of the FAO.

ESTIMATION OF VEGETATION DAMAGE DUE TO ASH FALL IN MT. PINATUBO AREA USING MOS-1 DATA

Genya Saitou, Arlene M. Evangelista (Soil Research and Development Center, Quezon City, Philippines.), and John A. Grace *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 252-255 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

An overview of the monitoring of the northern part of Luzon Island in the Philippines and estimation of vegetation damages caused by the ash falling from Mt. Pinatubo using the MOS-1 (Marine Observation Satellite-1)/MESSR (Multispectral Electronic Self-Scanning Radiometer) before and after the Mt. Pinatubo eruption is presented. In the multi-temporal analysis, the data acquired on both pre- and post-eruption were used for evaluating the extent of volcanic ash damage. Formulas used for analyses, such as radiometric correction of sun elevation, vegetation indices, and determination of the extent of damage are described. The application of satellite image analysis to natural disaster damage evaluation of ash damaged (90 to 100 percent of vegetation degraded) had attained as much as 200,000 ha in analyzing the data of three weeks after the eruption. This value decreased to about 40,000 ha, but the total of more than 30 percent damaged area still remained more than 200,000 ha at the time of four months after eruption. Author (NASDA)

N94-14260# Bangladesh Space Research and Remote Sensing Organization, Dhaka.

MANGROVE AFFORESTATION MONITORING USING REMOTE SENSING

A. K. M. Fariduddin Bhuiyan and M. Jinnahtul Islam *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 256-265 (For primary document see N94-14209 02-43)

Avail: CASI HC A02/MF A04

An overview of the mangrove afforestation monitoring conducted by the SPARRSO (Bangladesh Space Research and Remote Sensing Organization) using satellite remote sensing data is presented. The first five year program of afforestation to construct forest protection belt under the World Bank's financial assistance to protect life and property from the ravages of cyclones and storm surges were implemented by the Bangladesh Forest Department during the project period of 1980 to 1985. Several other projects of the mangrove afforestation project were the stabilization of the newly accredited lands by plantations and conservation of the stabilized lands from erosion and acceleration of the process of further land accretion in the Bay of Bengal. The ultimate objectives is to reclaim agricultural land within the zone of plantation areas, increase production of fuel wood and timber for industrial and constructional uses, increase the

total forest area and improve the socio-economic condition of the coastal population, and coastal plantation monitoring and mapping using satellite remote sensing data are outlined. Author (NASDA)

GEOPHYSICAL VALIDATION OF ATSR SEA SURFACE TEMPERATURES **c48**
I. J. Barton, D. T. Llewellyn-Jones (Rutherford Appleton Lab., Chilton, England.), A. J. Prata, and R. P. Cechet *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 278-281 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

The Along Track Scanning Radiometer (ATSR), which was launched on the ERS-1 in 1991, is supplying global Sea Surface Temperature (SST) measurements which are useful for climate research applications. To ensure that the radiometer is able to supply highly accurate estimates of SST, several cruises have been undertaken in Australian waters during which ship based measurements have been compared to those from space. A summary of this intercomparison is given along with a case study of comparisons between the ship measurements and those made using data from the Advanced Very High Resolution Radiometer (AVHRR) on the NOAA-11 meteorological satellite. Author (NASDA)

N94-14264# Iwate Univ., Morioka (Japan). Dept. of Computer and Information Science.
ACCURACY VALIDATION TEST OF ESTIMATED SEA SURFACE TEMPERATURE BY SATELLITE DATA **c48**
Sumio Tanba, Takashi Souma, Isao Yoshida, Takashi Watanabe, and Ryuuzou Yokoyama *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 282-285 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

By using the sea truth data of MBAMMBS (Mutsu Bay Automatic Marine Monitoring Buoy System), the accuracy of the SST (Sea Surface Temperature) estimated by the NOAA-11/AVHRR (Advanced Very High Resolution Radiometer) data was evaluated. An SST estimation function was calculated by the regression analysis based on the SWM (Split Window Method), and it provided the standard error of 0.70 C. Some match-ups were found to be exposed to strong SSE (Sea Surface Effect): that means the large temperature difference between the sea skin for the satellite detection and the 1 m depth of the buoy detection. By removing those match-ups, a regression function, whose coefficients are almost equal to those in the regression function by NOAA-9/AVHRR in Mutsu Bay, with the standard error of 0.36 C is obtained. SEA SURFACE EFFECT ON THE SEA SURFACE TEMPERATURE ESTIMATION BY SATELLITE DATA **c48**
Ryuuzou Yokoyama, Sumio Tanba, and Takashi Souma *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 286-289 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

By using a Sea Surface Temperature Profiler Buoy (SSTPB), the behavior of the vertical temperature profile was observed in Mutsu Bay. In the midday under clear and calm condition in summer, there occurred a large temperature difference, of at most 5 C, between the sea skin and the 1 m depth. The difference suddenly disappeared when it began to blow more than 5 m/s. The sea surface effect must be a dominant error factor in the Sea Surface Temperature (SST) estimation by satellite data other than the atmospheric effect. Author (NASDA)

ON THE SEA TRUTH DATA OF THE KUROSHIO MEANDER AND COLD EDDY MOVEMENT **c48**
Masataka Hishida and Yutaka Michida *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 290-298 (For primary document see N94-14209 02-43)
Avail: CASI HC A02/MF A04

An overview of observed phenomena of the KLM (Kuroshio Large Meander), relationship of sea level difference in the Tokara Strait where the ocean condition is strongly affected by that in the ECS (East China Sea), and formation of TCW (Tanegashima Cold Water) and KLM are presented. A new schematic representation of the ocean current system in the ECS obtained by compiling the knowledge derived from satellite IR (Infrared) image data provided by the MOS-1 (Marine Observation Satellite-1) and NOAA is proposed. The quick bulletin about the ocean condition named 'Kaiyou Sokuhou', and trajectories of surface drifters, an oceanographic atlas of the Japan-China Joint Research Program on the Kuroshio (JRK), and many other references are also proposed. The SST (Sea Surface Temperature) image in spring is useful to analyze the Kuroshio meander because TCW formation occurs, and this phenomenon will trigger the formation of the KLM. SST images from satellite show many changes of time dependent eddy movements. The satellite image data suggest that new physical ocean process or theory has to be considered.

TRACKING OF CHANGE OF A WARM-CORE RING STRUCTURE **c48**
Denzou Inagake and Akira Tomosada *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 299-302 (For primary document see N94-14209 02-43)
Avail: CASI HC A01/MF A04

A warm streamer, which was observed by a hydrographic survey onboard the research vessel Soyo Maru from May 20 to 22 in 1989, was tracked by MOS-1 (Marine Observation Satellite-1) VTIR (Visible and Thermal Infrared Radiometer) images and NOAA-10/AVHRR (Advanced Very High Resolution Radiometer) images from February to August in 1989. These images presented a generation of the streamer, spiraling warm water into the Kuroshio warm core ring, and development of the ring. The warm streamer around the Kuroshio warm core ring had a structure beyond 500 m in depth with a geostrophic current structure. Also, another warm streamer

was observed in the warm core ring. It can be considered that the inner streamer was taken into the warm core ring several weeks before and that the spiraling outer warm band was a new warmstreamer around the Kuroshio warm core ring. Author (NASDA)

WARM STREAMERS EXTENDED FROM WARM CORE RINGS (WCR'S) AND THEIR ROLE ON FISH MIGRATION AND FISHING GROUND FORMATION **c48**

Hideo Tameishi and Takeshige Sugimoto (Tokyo Univ., Japan.) *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 311-316 (For primary document see N94-14209 02-43)

Avail: CASI HC A02/MF A04

It is recognized that the Warm Streamers (WS's) often branch out toward the north or northwest from Warm Core Rings (WCR's), in satellite thermal imageries. They become migrating paths toward the North and from offshore to nearshore. In this study, the relationship between these fine structures and fishing grounds, were investigated, using NOAA/AVHRR (Advanced Very High Resolution Radiometer) data with assistance of aircraft data and fisheries information. The obtained results are as follows: (1) NOAA/AVHRR imageries with spatial resolution of 1.1 km represent the structures of the WS's of about 10 km in width around the WCR's well; (2) by using the simultaneous aircraft data, many sardine's schools are recognized at the head of WS, in which coastal region sardine's fishing grounds are often formed; (3) it seems that WS is useful for the transfer of schools toward the coast; and (4) schools of sardine, mackerel, and other species make zonation across the front of WCR's. ATMOSPHERIC CORRECTION FOR SEA SURFACE TEMPERATURE BY APPLICATION OF MICROWAVE DUAL-CHANNEL TECHNIQUE TO VTIR DATA **c48**

Youzou Takayama *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 317-320 (For primary document see N94-14209 02-43)

Avail: CASI HC A01/MF A04

Atmospheric correction for estimating sea surface temperature (SST) from VTIR data by using the IR split-window technique (11 and 12 microns) and dual-frequency microwave channels (23.8 and 31.4 GHz) are presented. Both methods have the same capability for correcting the water-vapor absorption effect to estimate SST. However, the microwave dual-frequency method bring better SST estimation than the split-window technique for VTIR data. The simulation study shows that this better estimation of SST by the microwave dual-frequency is due to a better signal-to-noise ratio for correction of atmospheric absorption than the split-window technique, in the case of VTIR observation. By using the different radiation characteristics between infrared and microwave channels, it is feasible to improve the accuracy in estimating the SST in the case of the existing dense stratospheric aerosol. Avail: CASI HC A01/MF A04

An overview of the space transportation aspects of the ESA (European Space Agency) programs as they result from history, present status, and decisions taken at the ministerial level conference in Granada, Spain is presented. The new factors taken into consideration for the long term plan proposed in Munich, Germany, the three strategic options for the reorientation of the ESA long term plan, and the essential elements of space transportation in the Granada long term plan in three areas of space activities, scientific, and commercial launches with expendable launch vehicles, manned flight and in-orbit infrastructure, and future transportation systems are outlined. The new ESA long term plan, in the field of space transportation systems, constitutes a reorientation of the initial program contemplated in previous councils at ministerial level. It aims at balancing the new economic situation with the new avenues of cooperation, and the outcome will be a new implementation of the space transportation systems policy.

THE STATUS OF THE HOPE CONCEPT STUDY **c16**

Jirou Kouchiyama and Akihiro Eguchi *In* Science and Technology Agency, Asia-Pacific ISY Conference, Volume 2 31 Mar. 1993 p 369-374 (For primary document see N94-14209 02-43)
Avail: CASI HC A02/MF A04

National Space Development Agency of Japan (NASDA) has been studying an unmanned winged vehicle called the H-2 Orbiting Plane (HOPE). The HOPE will be launched by H-2 launch vehicle or H-2 derivative launch vehicle, and injected into low orbit. After a few days stay in space for access to the space station, HOPE will de-orbit and go back to a named landing site automatically. The concept of the 10-ton class vehicle launched by H-2 launch vehicle was prepared in 1988. However, its payload capability is not enough for the practical use of the space station expected at the beginning of the 21st century. Therefore, the concept of 20-ton class vehicle launched by the Solid Rocket Booster (SRB)-added H-2 launch vehicle without the second stage (Liquid Engine-5A (LE-5A) engine) was studied in 1989. This vehicle will be injected into low orbit by its own propulsion system. Its payload capability was estimated at 3 tons. In the study from 1990 to 1991, it was revealed that the reduction of the HOPE weight is the most important problem. At present, the shapes of the main wing, the orbital injection systems (reusable engine or expendable one), and the materials of the main structure (carbon/polyimide) are being studied to reduce the weight. This report overviews the current research of space communications technology in Communications Research Laboratory (CRL), Ministry of Posts, and Telecommunications. The Engineering Test Satellite-5 (ETS-5) project has been conducted these five years for mobile communications development. The international cooperations using ETS-5 has been performed. It describes the project of Communications and Broadcasting Engineering Test Satellite (COMETS) to be launched in 1997 for experiments of advanced mobile satellite communication and advanced broadcasting. It also mentions the project of Engineering Test Satellite-6 (ETS-6), to be launched in 1994, in which the CRL's missions of ETS-6 are the inter-satellite communication of S-band, millimeter-wave, and optical. Finally, this report describes the technologies of large antenna assembly experiment, small satellite communications, and cluster satellite briefly. Author (NASDA)

The analysis and enhancement of the methods employed in supervised classification in remote sensing is addressed. An implementation of the maximum likelihood method on the basis of a per class principal component transformation is suggested. This efficient implementation is also robust in the case of ill conditioned covariance matrices. A generalization of the maximum likelihood method is proposed which can be used for highly correlated (multi-collinear) features of high dimension. It is also suggested to allow class specific selections of features. This makes it possible to discard features showing non-normal distribution on a class by class basis. These generalizations require a normalization of distance measures across all feature spaces (possibly of different dimension). As a tool for this normalization, the paradigm of fuzzy set theory is suggested: distance measures are mapped into grades of memberships to individual classes. This leads to fuzzy classification methods: a vector of memberships to the various classes is assigned to each pixel. Besides the possibility of using different features and different classificators within a single classification run, a new approach to multitemporal classification is emerging. A method for implementing a geocoded thematic database is discussed and a method for detecting and resolving mixed pixels is proposed. A context sensitive reclassification method is presented which is particularly useful in the case of sensor data of high spatial resolution. The effectiveness of this method is demonstrated for synthetic data as well as thematic mapper data. A comparison with probabilistic relaxation method and classification after segmentation shows that the new method is a significant improvement in utilizing context in reclassification. ESA

(DE93-012605; UCRL-JC-112103; CONF-9210231-4) Avail: CASI HC A02/MF A01

Given multiple images of the surface of the earth from dual-band infrared sensors, our system fuses information from the sensors to reduce the effects of clutter and improve the ability to detect buried or surface target sites. Supervised learning pattern classifiers (including neural networks) are used. We present results of experiments to detect buried land mines from real data and evaluate the usefulness of fusing information from multiple sensor types. The novelty of the work lies mostly in the combination of the algorithms and their application to the very important and currently unsolved problem of detecting buried land mines from an airborne standoff platform. OBTAINING DIGITAL REGIONAL PLANNING INFORMATION FROM AERIAL PICTURES [VERKRIJGEN VAN DIGITALE RUIMTELIJKE INFORMATIE UIT LUCHTFOTO'S]
B. J. vanBleek and P. G. Lentjes 1992 58 p In DUTCH
(Rept-228; ETN-93-94093) Copyright Avail: CASI HC A04/MF A01

The use of aerial photography for digital regional planning information and the role of scanning therein was investigated. Digitizing the information from aerial pictures allows a vector inventory to be obtained. Digitation can be performed by single picture mapping or stereomapping. For digitation from a screen the aerial picture has first to be scanned. Scanned aerial pictures can be used for digital terrain models, digital orthophotos, visual support of other digital regional planning information, and digitation of vector information. Aerial pictures can be used for orientation in the field, geometric information, thematic information, and geographic information systems. The combination of geometric and thematic information provides an object oriented terrain description. ESA

THE 1992 JSEE/JWEA JOINT CONFERENCE
3 Dec. 1992 305 p In JAPANESE Conference held in Osaka, Japan, 3-4 Dec. 1992 Prepared in cooperation with Japan Wind Energy Association, Tokyo
(DE93-793955; CONF-921276) Avail: CASI HC A14/MF A03

The proceedings of the conference include the results of research and development of the photovoltaic power generation system, the wind power generation and biomass. As for the photovoltaic power generation system, reports are made on the following: power generation efficiency of the system, output characteristics of solar cell module, interconnected power system, optical properties of solar cells, solar cell array, development of intermittent flow redox batteries to be used for the photovoltaic power generation system. As to solar radiation utilization, studies on the following are made public: an optical/thermal hybrid heat collector which is designed to obtain light and heat at the same time using a solar cell as a heat collecting board, solar car, a silica gel layer used in a solar thermal utilization direct regenerating type adsorption tank, a solar greenhouse, a solar refrigerating system, solar pond, a solar energy ground thermal storage system, a solar-cell blade wind turbine as a composite system, photovoltaic-thermo composite pannels, solar house, passive solar heating. A small wind turbine generation system for mountainous regions is described. As biomass, production of tall-golden-rod is reported. DOE

PHOTOVOLTAIC SUBCONTRACT PROGRAM
Mar. 1993 319 p
(Contract DE-AC02-83CH-10093)
(DE93-000092; NREL/TP-410-5335) Avail: CASI HC A14/MF A03

This report summarizes the FY-92 progress of the subcontracted photovoltaic (PV) research and development (R&D) performed under the Photovoltaic Advanced Research and Development Project at the National

Renewable Energy Laboratory (NREL)--formerly the Solar Energy Research Institute (SERI). The mission of the national PV program is to develop PV technology for large-scale generation of economically competitive electric power in the United States. The technical sections of the report cover the main areas of the subcontract program: the Crystalline Materials and Advanced Concepts project, the Polycrystalline Thin Films project, Amorphous Silicon Research project, the Photovoltaic Manufacturing Technology (PVMaT) project, PV Module and System Performance and Engineering project, and the PV Analysis and Applications Development project. Technical summaries of each of the subcontracted programs provide a discussion of approaches, major accomplishments in FY-92, and future research directions. DOE

(Contract DE-AC02-83CH-10093)
(DE93-000093; DOE/CH-10093/210) Avail: CASI HC A06/MF A02

US DOE's Photovoltaics Program has helped photovoltaic technologies evolve from materials and concepts in laboratories to competitive products rolling off automated assembly lines. The program is working to expand industrial capacity while continuing basic and applied technology R and D. This document is a tabulation of photovoltaics R and D that were begun, continued, or completed during this period. National laboratories or industrial, academic, and nonprofit research institutions perform the R and D activities. The document is organized first by directing organization, then by project title and individual task. Each listing provides the name of contractor, period of performance, funding, objectives, accomplishments, and FY 1993 milestones. An index of contractors is included. DOE

TECHNOLOGY ASSESSMENTS OF ADVANCED ENERGY STORAGE SYSTEMS FOR ELECTRIC AND HYBRID VEHICLES
30 Apr. 1993 117 p
(Contract DE-AC01-91CE-50337)
(DE93-014395; DOE/CE-50337/T1) Avail: CASI HC A06/MF A02

Flywheels, hydropneumatic accumulators (in vehicles with a hydrostatic powertrain), and superconducting magnets were assessed as candidate technologies for recovering braking energy and averaging power demands in electric and hybrid vehicles. The technologies were also assessed for their suitability for fulfilling the entire energy storage requirement in vehicles. The scope of the technology assessments included the current state-of-the-art and developments anticipated within the next few years in the US and abroad. Key individuals and companies currently working on each technology contributed technical information to the study. Some of these individuals and companies are nearing the pre-production prototype stage with systems suitable for automobiles. Several have constructed systems using similar technology for other applications, including satellites and industrial equipment. DOE

CARBONATE FUEL CELL ENDURANCE: HARDWARE CORROSION AND ELECTROLYTE MANAGEMENT STATUS
C. Yuh, R. Johnsen, M. Farooque, and H. Maru 1993 15 p Presented at the 183rd Electrochemical Society Meeting, Honolulu, HI, 16-21 May 1993
(Contract DE-AC21-90MC-27168)
(DE93-013800; DOE/MC-27168/93/C0188; CONF-930571-13) Avail: CASI HC A03/MF A01

Endurance tests of carbonate fuel cell stacks (up to 10,000 hours) have shown that hardware corrosion and electrolyte losses can be reasonably controlled by proper material selection and cell design. Corrosion of stainless steel current collector hardware, nickel clad bipolar plate and aluminized wet seal show rates within acceptable limits. Electrolyte loss rate to current collector surface has been minimized by reducing exposed current collector surface area. Electrolyte evaporation loss appears tolerable. Electrolyte redistribution has been restrained by proper design of manifold seals. DOE

SURFACTANT STUDIES FOR BENCH-SCALE OPERATION Quarterly Technical Progress Report No. 1, 1 Jul. - 30 Sep. 1992
Gregory S. Hickey and Pramod K. Sharma 30 Dec. 1992 13 p
(Contract DE-AI21-92PC-92150)
(NASA-CR-194097; JPL-Publ-92-30; NAS 1.26:194097) Avail: CASI HC A03/MF A01

A phase 2 study was initiated to investigate surfactant-assisted coal liquefaction, with the objective of quantifying the enhancement in liquid yields and product quality. This publication covers the first quarter of work. The major accomplishments were: the refurbishment of the high-pressure, high-temperature reactor autoclave, the completion of four coal liquefaction runs with Pittsburgh #8 coal, two each with and without sodium lignosulfonate surfactant, and the development of an analysis scheme for the product liquid filtrate and filter cake. Initial results at low reactor temperatures show that the addition of the surfactant produces an improvement in conversion yields and an increase in lighter boiling point fractions for the filtrate. PROMOTION OF GEOTHERMAL ENERGY DEVELOPMENT IN 1991 Survey Report No. 30
Jan. 1993 31 p In JAPANESE
(DE93-799057; ETDE/JP-MF-93799057) Avail: CASI HC A03/MF A01

The paper investigates how hot springs are affected by drilling of environmental survey wells and blowout/injection of geothermal fluids which are incidental to the geothermal energy development in the Hakkoda west area. The hot springs in the survey are classified as follows: Sukayu hot springs; acidity-containing Al-Ca-SO4 spring, Jogakura No. 2 spring, Na-HCO3(center dot)Cl(center dot)SO4 type simple spring, Jogakura No.3 spring; alcaline/Na-HCO3 type simple spring, Kansuizawa hot spring; and Na-HCO3, Cl spring. As compared with the environmental survey in fiscal 1989 before blowout, the hot springs except the Jogakura No. 3 spring were relatively smaller in variations and brought almost stabilized results. Moreover, large variations in each survey item relating to the Jogakura No. 3 spring agreed with those at the time of stopping pumping facilities due to reduction in output of hot water, and it is hard to think that it was caused by drilling of geothermal exploratory wells. Accordingly, there are no observed effects of drilling for geothermal exploration on the neighboring hot springs. For geothermal survey, however, it is desirable to investigate hydrologic structures and then to take measures such as injection of all geothermal water into the depth of the underground. DOE

PROMOTION OF GEOTHERMAL ENERGY DEVELOPMENT IN 1991 Survey Report No. 31
Jan. 1993 37 p In JAPANESE
(DE93-799058; ETDE/JP-MF-93799058) Avail: CASI HC A03/MF A01

The paper investigates hot springs in fumarolic gas in the Iwatesan west area and evaluates effects of regional development on the neighboring environment. Details of each spring--PH, total evaporation residue, and spring quality--are as follows: 7.8, 2190mg/l, and Ca(center dot)Mg-HCO3(center dot)SO4 spring for Water well No. 18; 7.4, 1285mg/l, and Na-HCO3(center dot) Cl spring for Genbu hot spring; 7.6, 471mg/l, and Na(center dot)Ca-HCO3 type simple spring for Nukumori hot spring; and 2.9, 461mg/l, and acidity-Ca-SO4 type simple spring for Matsukawa hot spring. Variations are smaller than those in fiscal 1989. Only the

Matsukawa hot spring has a large variation in its output of hot water, but a coefficient of its correlation with precipitation is 0.38. When installing a geothermal power plant, it is necessary to investigate the injection of geothermal water into the ground, hydrologic structures, etc. and to give careful consideration to the effect of the development on the sources of the hot spring. REFLECTIVE COATINGS FOR SOLAR APPLICATIONS
G. Jorgensen May 1993 9 p Presented at the 36th Annual Society of Vacuum Coaters Technical Conference, Dallas, TX, 27-29 Apr. 1993
(Contract DE-AC02-83CH-10093)
(DE93-010026; NREL/TP-471-5536; CONF-9304149-1) Avail: CASI HC A02/MF A01

Many applications of solar energy require large mirrors to provide high levels of concentrated sunlight. The success of such conversion systems hinges on the optical durability and economic viability of the reflector materials. A major effort at the National Renewable Energy Laboratory (NREL) has been to improve the existing reflector materials technology and to identify candidates that retain optical performance and durability criteria and offer potential for reduced cost. To attain the goals, it is desirable to maintain and increase the involvement of industrial organizations in reflective materials R&D related to the conversion of solar resources to useful energy. Toward this end, NREL has recently initiated several collaborative efforts with industry to develop advanced reflector materials. DOE

LOW TEMPERATURE METAL-ORGANIC CHEMICAL VAPOR DEPOSITION GROWTH PROCESSES FOR HIGH EFFICIENCY SOLAR CELLS Ph.D. Thesis, 1988 Final Technical Report, 1 Sep. 1985 - 30 Nov. 1989
Qisheng Chen and P. D. Dapkus (California Univ., Los Angeles.) Feb. 1993 288 p
(Contracts DE-AC02-83CH-10093; N00014-89-J-1229)
(DE92-010562; NREL-TP-451-4853) Avail: CASI HC A13/MF A03

This report describes the results of a program to develop a more complete understanding of the physical and chemical processes involved in low-temperature growth of III-V compounds by metal-organic chemical vapor deposition (MOCVD) and to develop a low-temperature process that is suitable for the growth of high-efficiency solar cells. The program was structured to develop a better understanding of the chemical reactions involved in MOCVD growth, to develop a model of the processes occurring in the gas phase, to understand the physical kinetics and reactions operative on the surface of the growing crystal, and to develop an understanding of the means by which these processes may be altered to reduce the temperature of growth and the utilization of toxic hydrides. The basic approach was to develop the required information about the chemical and physical kinetics operative in the gas phase and on the surface by the direct physical measurement of the processes whenever possible. The program included five tasks: (1) MOCVD growth process characterization; (2) photoenhanced MOCVD studies; (3) materials characterization; (4) device fabrication and characterization; and (5) photovoltaic training. Most of the goals of the program were met and significant progress was made in defining an approach that would allow both high throughput and high uniformity growth of compound semiconductors at low temperatures. The technical activity was focused on determining the rates of thermal decomposition of trimethyl gallium, exploring alternate arsenic sources for use MOCVD, and empirical studies of atomic layer epitaxy as an approach. ELECTROCATALYSIS ISSUES IN POLYMER ELECTROLYTE FUEL CELLS
M. S. Wilson, C. R. Derouin, J. A. Valerio, and S. Gottesfeld 1993 7 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, Atlanta, GA, 8-13 Aug. 1993
(Contract W-7405-eng-36)
(DE93-014450; LA-UR-93-1689; CONF-930804-2) Avail: CASI HC A02/MF A01

Various electrocatalysis issues of importance to low platinum loading polymer electrolyte fuel cells (PEFCs) are discussed. Thin film catalyst layer assemblies are used to investigate the effects of CO and CO2 on the anode as well as efforts to restore performance by oxygen bleeding into the anode feedstream. These electrodes behave differently than ionomer-impregnated E-TEK electrodes because of the extra, exposed Pt in the latter case. The tolerance of Pt-Ru alloy thin film anodes to CO and CO2 are also evaluated. Thin film electrodes are also used to study Pt particle growth in aged electrodes as well as particle size effects on specific activity. DOE

HOT DRY ROCK ENERGY Annual Report, Fiscal Year 1992
W. W. Winchester, ed. Apr. 1993 80 p
(Contract W-7405-eng-36)
(DE93-014452; LA-UR-93-1678) Avail: CASI HC A05/MF A01

Hot Dry Rock technology took a giant leap forward this year as the long-awaited long-term flow test (LTFT) of the Phase 2 HDR reservoir at Fenton Hill got underway. Energy was produced on a twenty-four hour a day basis for a continuous period of nearly four months of steady-state testing. Hot water was brought to the surface at 90-100 gallons per minute (gpm) with temperatures of 180 C (356 F) and higher. During that time, the HDR plant achieved an on-line record of 98.8%. Surface temperature measurements and temperature logging deep within the wellbore confirmed that no decline in the average temperature of fluid produced from the reservoir occurred. Tracer experiments indicated that flow paths within the reservoir were undergoing continuous change during the test. Remarkably, it appeared that longer flow paths carried a larger proportion of the flow as the test proceeded, while more direct fluid pathways disappeared or carried a significantly reduced flow. In sum, access to hot rock appeared to improve over the span of the test. Water losses during the test averaged 10-12% and showed a slow long-term decline. These results confirmed what had been previously discovered in static pressurization testing: water consumption declines significantly during extended operation of an HDR reservoir. In combination with a recent demonstration by the Japanese that water losses can be greatly reduced by the proper placement of multiple production wells, the recent results at Fenton Hill have effectively demonstrated that excessive water consumption should not be an issue for a properly engineered HDR facility at a well chosen site. FIELD OF SOLAR COLLECTORS: EFFECT OF SHADOWING ON THE OPTIMAL FIELD DESIGN M.S. Thesis
Marcos Crutchik Jan. 1992 216 p
(ITN-93-85197) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

For a field of solar energy collectors, the effects on energy output of mutual and self-shading of the collectors are analyzed, in relation to the physical parameters of the field. Among the parameters considered are the spacing between the collectors, the tilt and azimuth angles of the collectors and the slope and orientation of the field. The self-shading of convex and concave collectors and the special case of the new catenary-tent collector, conceived for eventual use on non-terrestrial planets are also considered. The results of the shading analysis are used to determine the optimal deployment of an arbitrarily oriented and sloped field of stationary collectors. The optimization criteria considered were: maximum energy output; minimum plant cost and minimum produced energy cost. The deployment

parameters considered for each of these criteria were number and spacing of rows and tilt angle of the collectors. For the first criterion a fixed field area was considered; for the other two, both fixed and unlimited land dimensions were considered. In every case, yearly average and worst month (January) insolation figures were considered. The optimizations based on maximum energy output or minimum energy cost led to higher initial plant costs, owing to the larger number of rows required, but led to lower costs of produced energy. The solution which minimized the plant cost led to the highest cost of produced energy. A sensitivity analysis covering all the parameters showed that variations in the individual collector parameters (collector height, length and efficiency) have the most effect on the optimal solution. THE 1.00 MeV PROTON RADIATION RESISTANCE STUDIES OF AMORPHOUS SILICON-BASED ALLOY SOLAR CELLS Ph.D. Thesis
Salman Saib Abdulaziz 1992 230 p
Avail: Univ. Microfilms Order No. DA9310613

Amorphous silicon based (a-Si) alloy solar cells have been proposed as candidates for space applications. However, before space-born applications of a-Si cells can take place, the influence of the harsh space environment on the cells operating characteristics needs to be determined. The focus of this work is to investigate and model the effects of 1.00 MeV proton irradiation in the fluence range 10(exp I4) to 10(exp I5) cm(exp -2) and their annealing in the temperature range 0 to 200 C on the current density-voltage (J-V) and quantum efficiency (QE) characteristics of a-Si solar cells. 1.00 MeV protons degrade the J-V characteristics of a-Si cells. Single-junction a-Si:H cells show higher radiation resistance than either single-junction a-Si(sub x)Ge(sub I-x):H or dual-junction a-Si:H cells. The J(sub SC) is related to the fluence and electron drift-length/i-layer thickness ratio. The FF and eta/eta(sub O) are modeled as a function of fluence. Our experimental results were generally found to be in harmony with our simple models. Significant annealing of the J-V characteristics were observed at temperatures of 0 C and 22 C. A one-hour anneal at 200 C restored the J-V characteristics of the a-Si cells to their virgin values. Using first-order kinetics, the annealing of Jsc, FF and Eta/Eta(sub O) were modeled as a function of fast and slow annealing defects, and good agreement was found. The 1.00 MeV protons degraded the QE in a non-uniform fashion. The peak of the QE shifted toward the blue end of the spectrum. The QE of the a-Si cells was modeled as a function of thickness and electron drift-length. The experimental data were found to be in acceptable agreement with our simple model. The J(sub SC) was calculated from the convolution of the QE and AM1.5G spectrum. An average error of 45.3 percent (QE measured without light bias), and 6.8 percent (light biased QE) was observed between the calculated and measured J(sub SC). The J(sub SC) under AM0 illumination was calculated from the measured J(sub SC) under AM1.5G illumination . Author

MATERIALS COMPATIBILITY OF HYDRIDE STORAGE MATERIALS WITH AUSTENITIC STAINLESS STEELS
E. A. Clark 21 Sep. 1992 26 p
(Contract DE-AC09-89SR-18035)
(DE93-013688; WSRC-TR-92-438) Avail: CASI HC A03/MF A01

This task evaluated the materials compatibility of LaNi(5-x)Al(x) (x= 0.3, 0.75) hydrides and palladium coated kieselguhr with austenitic stainless steel in hydrogen and tritium process environments. Based on observations of retired prototype hydride storage beds and materials exposure testing samples designed for this study, no materials compatibility problem was indicated. Scanning electron microscopy observations of features on stainless steel surfaces after exposure to hydrides are also commonly found on as-received materials before hydriding. These features are caused by either normal heat treating and acid cleaning of stainless steel or reflect the final machining operation. DOE

PERFORMANCE EFFECTS OF COAL-DERIVED CONTAMINANTS ON THE CARBONATE FUEL CELL
A. Pigeaud and G. Wilemski (Physical Sciences, Inc., Andover, MA.) 1993 20 p Presented at the 3rd International Symposium on Carbonate Fuel Cell Technology, Honolulu, HI, 16-21 May 1993
(Contract DE-AC21-90MC-27168)
(DE93-013801; DOE/MC-27168/93/C0189; CONF-9305101-1) Avail: CASI HC A03/MF A01

Coal-derived contaminant studies have been pursued at ERC since the early 1980's when the pace of carbonate fuel cell development began to markedly increase. Initial work was concerned with performance effects on laboratory and bench-scale carbonate fuel cells primarily due to sulfur compounds. Results have now also been obtained with respect to nine additional coal-gas contaminants, including volatile trace metal species. Thermochemical calculations, out-of-cell experiments, and cell performance as well as endurance tests have recently been conducted which have involved the following species: NH3, H2S (COS), HCl, AsH3(As2(v)), Zn(v), Pb(v), Cd(v), H2Se, Hg(v), Sn(v). Employing thermochemically calculated results, thermogravimetric (TGA) and pre-, and post-test analytical data as well as fuel cell performance observations, it has been shown that there are four main mechanisms of contaminant interaction with the carbonate fuel cell. These have been formulated into performance models for six significant contaminant species, thus providing long-term endurance estimations. DOE

THE LARGE AREA PULSED SOLAR SIMULATOR (LAPSS)
R. L. Mueller 15 Aug. 1993 12 p
(Contract NAS7-918)
(NASA-CR-194507; JPL-Publ-93-22; NAS 1.26:194507) Avail: CASI HC A03/MF A01

A Large Area Pulsed Solar Simulator (LAPSS) has been installed at JPL. It is primarily intended to be used to illuminate and measure the electrical performance of photovoltaic devices. The simulator, originally manufactured by Spectrolab, Sylmar, California, occupies an area measuring about 3 meters wide by 12 meters long. The data acquisition and data processing subsystems have been modernized. Tests on the LAPSS performance resulted in better than +/- 2 percent uniformity of irradiance at the test plane and better than +/- 0.3 percent measurement repeatability after warm-up. Glass absorption filters are used to reduce the level of ultraviolet light emitted from the xenon flash lamps. This provides a close match to standard airmass zero and airmass 1.5 spectral irradiance distributions. The 2 millisecond light pulse prevents heating of the device under test, resulting in more reliable temperature measurements. Overall, excellent electrical performance measurements have been made of many different types and sizes of photovoltaic devices. Author (revised)

NUMERICAL SIMULATION AND ANALYSIS OF ELECTRICAL AND OPTICAL PROPERTIES OF Al(x)Ga(1-x)As / GaAs Ph.D. Thesis [NUMERISCHE SIMULATION UND ANALYSE DER ELEKTRISCHEN UND OPTISCHEN EIGENSCHAFTEN VON ALXGA(1-X)AS/GAAS-SOLARZELLEN]
Heinz Eschrich 1992 123 p In GERMAN
(ETN-93-94387) Avail: CASI HC A06/MF A02

A numerical algorithm for description of gallium arsenide solar cells behavior with photovoltaic active window layer is developed. A partial nonlinear differential equation system, based on current, balance and Poisson equations, was solved using finite difference method. Spatial distributions of charge carrier concentration and potential were calculated using a recursive and iterative solution algorithm. Reflexion losses at all phase

boundaries were determined using a matrix method. Solution algorithm was tested considering results of an analytical model of a solar cell with abrupt pn transition. From results of analytic optimization calculations, an improved structure was obtained, with a thinner emitter of 820 nm. The influence of surface and boundary recombination, diffusion length and cell geometry on spectral internal quantum efficiency was simulated. ESA

CONTINUOUS ROLL-TO-ROLL a-Si PHOTOVOLTAIC MANUFACTURING TECHNOLOGY

M. Izu Apr. 1993 52 p Prepared in cooperation with Energy Conversion Devices, Inc., Troy, MI

(Contract DE-AC02-83CH-10093)

(DE93-010006; NREL/TP-411-5453) Avail: CASI HC A04/MF A01

This report describes work performed by ECD to accomplish the following goals: to advance its roll-to-roll, triple-junction photovoltaic manufacturing technologies; to reduce the module production costs; to increase the stabilized module performance; and to expand the commercial capacity utilizing ECD technology. The 3-year goal is to develop advanced large-scale manufacturing technology incorporating ECD's earlier research advances with the capability of producing modules with stable 11% efficiency at a cost of approximately $1/W(sub p). Major efforts during Phase 1 are as follows: (1) the optimization of the high-performance back-reflector system, (2) the optimization of a-Si-Ge narrow band-gap solar cell, and (3) the optimization of the stable efficiency of the module. The goal is to achieve a stable 8% efficient 0.3-m (times) 1.2-m (1-ft (times) 4-ft) module. Also, the efforts include work on a proprietary, high-deposition-rate, microwave plasma, CVD manufacturing technology and on the investigation of material cost reduction. DOE

OPTIMIZATION OF TRANSPARENT AND REFLECTING ELECTRODES FOR AMORPHOUS SILICON SOLAR CELLS

R. G. Gordon Apr. 1993 101 p Prepared in cooperation with Energy Conversion Devices, Inc., Troy, MI

(Contract DE-AC02-83CH-10093)

(DE93-010009; NREL/TP-411-5456) Avail: CASI HC A06/MF A02

This report describes work to improve the performance of solar cells by improving the electrical and optical properties of their transparent conducting oxide (TCO) layers. Boron-doped zinc-oxide films were deposited by atmospheric pressure chemical vapor deposition in a laminar-flow reactor from diethyl zinc, tert-butanol, and diborane in the temperature range between 300 C and 420 C. When the deposition temperature was above 320 C, both doped and undoped films have highly oriented crystallites with their c-axes perpendicular to the substrate plane. Films deposited from 0.07% diethyl zinc and 2.4% tert-butanol have electron densities between 3.5 x 10(exp 20)/cu cm and 5.5 x 10(exp 20)/cu cm, conductivities between 250/Omega and 2500/Omega and mobilities between 2.5 sq cm/V-s and 35.0 sq cm/V-s, depending on dopant concentration, film thickness, and deposition temperature. Optical measurements show that the maximum infrared reflectance of the doped films is close to 90%, compared to about 20% for undoped films. Film visible absorption and film conductivity were found to increase with film thickness. The ratio of conductivity to visible absorption coefficient for doped films was between 0.1 Omega and 1.1/Omega. The band gap of the film changes from 3.3 eV to 3.7 eV when the film is doped with 0.012% diborane. DOE

SIMULATING THE DAYLIGHT PERFORMANCE OF FENESTRATION SYSTEMS AND SPACES OF ARBITRARY COMPLEXITY: THE IDC METHOD

K. Papamichael and L. Beltran Apr. 1993 5 p Presented at the 3rd International Conference of the International Building Performance Simulation Association, Adelaide, Australia, 16-18 Aug. 1993

(Contract DE-AC03-76SF-00098)

(DE93-015177; LBL-33945; CONF-9308111-1) Avail: CASI HC A01/MF A01

A new method to simulate the daylight performance of fenestration systems and spaces is presented. This new method, named IDC (Integration of Directional Coefficients), allows the simulation of the daylight performance of fenestration systems and spaces of arbitrary complexity, under any sun, sky, and ground conditions. The IDC method is based on the combination of scale model photometry and computer-based simulation. Physical scale models are used to experimentally determine a comprehensive set of 'directional illuminance coefficients' at reference points of interest, which are then used in analytical, computer-based routines, to determine daylight factors or actual daylight illuminance values under any sun, sky, and ground conditions. The main advantage of the IDC method is its applicability to any optically complex environment. Moreover, the computer-based analytical routines are fast enough to allow for hourly simulation of the daylight performance over the course of an entire year. However, the method requires appropriate experimental facilities for the determination of the Directional Coefficients. The IDC method has been implemented and used successfully in inter-validation procedures with various daylight simulation computer programs. Currently, it is used to simulate the daylight performance of fenestration systems that incorporate optically complex components, such as Venetian blinds, optically treated light shelves and light pipes. PHOTOVOLTAIC ADVANCED RESEARCH AND DEVELOPMENT PROJECT: SOLAR RADIATION RESEARCH Annual Report, 1 Oct. 1990 - 30 Sep. 1991

R. Hulstrom, T. Cannon, T. Stoffel, and C. Riordan Oct. 1992 17 p

(Contract DE-AC02-83CH-10093)

(DE92-016430; NREL/TP-411-5013) Avail: CASI HC A03/MF A01

This report is a summary of 1991's research activities and results under the Solar Radiation Research task of the Photovoltaic (PV) Advanced Research and Development project at the National Renewable Energy Laboratory (NREL). This task directly supports the characterization, testing, and design of PV cells modules, and systems. The development of a scientific and engineering understanding of incident (i.e., available to PV devices) solar irradiance and the appropriate instrumentation systems and measurement methods are the activities and results of this project. Activities described in this report include the completion of the Atmospheric Optical Calibration Systems (AOCS) and the comparison of instrumentation systems that collect site-specific measurements of solar irradiance for the purpose of PV system feasibility studies and/or design. STATUS OF SOFC DEVELOPMENT IN USA

D. T. Hooie 1993 5 p Presented at the 3rd International Symposium on Carbonate Fuel Cell Technology, Honolulu, HI, 16-21 May 1993

(DE93-015568; DOE/METC-C/93/7083; CONF-9305101-3) Avail: CASI HC A01/MF A01

Solid oxide fuel cells represent a highly efficient power generation/cogeneration source in the United States and worldwide. Currently, the US is a leader in this technology in the tubular, monolithic, and planar solid oxide fuel cell areas. In addition, research is being conducted in intermediate temperature solid oxide fuel cells. An overview of the status of these technologies, research, and critical issues is presented. DOE

INFLOW CHARACTERISTICS ASSOCIATED WITH HIGH-BLADE-LOADING EVENTS IN A WIND FARM

N. D. Kelley Jul. 1993 12 p Presented at the 25th IEA Experts Meeting: Increased Loads in Wind Power Stations, Wind Farms, Gothenburg,

Sweden, 3-4 May 1993
(Contract DE-AC02-83CH-10093)
(DE93-010042; NREL/TP-442-5623; CONF-9305243-1) Avail: CASI HC A03/MF A01

The stochastic characteristics of the turbulent inflow have been shown to be of major significance in the accumulation of fatigue in wind turbines. Because most of the wind turbine installations in the U.S. have taken place in multi-turbine or windfarm configurations, the fatigue damage associated with the higher turbulence levels within such arrangements must be taken into account when making estimates of component service lifetimes. The simultaneous monitoring of two adjacent wind turbines over a wide range of turbulent inflow conditions has given the authors more confidence in describing the structural load distributions that can be expected in such an environment. The adjacent testing of the two turbines allowed the authors to postulate that observed similarities in the response dynamics and load distributions could be considered quasi-universal, while the dissimilarities could be considered to result from the differing design of the rotors. The format has also allowed them to begin to define appropriate statistical load distribution models for many of the critical components in which fatigue is a major driver of the design. In addition to the adjacent turbine measurements, they also briefly discuss load distributions measured on a teetered-hub turbine. DOE

EXPERIMENTAL INSTRUMENTATION SYSTEM FOR THE PHASED ARRAY MIRROR EXTENDIBLE LARGE APERTURE (PAMELA) TEST PROGRAM Final Report, 10 May - 30 Sep. 1993
William H. Boykin, Jr. 30 Sep. 1993 19 p
(Contract NAS8-39218)
(NASA-CR-194421; NAS 1.26:194421; TR-HSV-93-0002) Avail: CASI HC A03/MF A01

Adaptive optics are used in telescopes for both viewing objects with minimum distortion and for transmitting laser beams with minimum beam divergence and dance. In order to test concepts on a smaller scale, NASA MSFC is in the process of setting up an adaptive optics test facility with precision (fraction of wavelengths) measurement equipment. The initial system under test is the adaptive optical telescope called PAMELA (Phased Array Mirror Extendible Large Aperture). Goals of this test are: assessment of test hardware specifications for PAMELA application and the determination of the sensitivities of instruments for measuring PAMELA (and other adaptive optical telescopes) imperfections; evaluation of the PAMELA system integration effort and test progress and recommended actions to enhance these activities; and development of concepts and prototypes of experimental apparatuses for PAMELA. Methane monooxygenase (MMO) is an enzyme found in methanotrophs that catalyses the selective oxidation of methane to methanol. MMO is protein complex one component of which is a binuclear metal center containing oxygenase. We have completed one round of a design/synthesis/evaluation cycle in the development of coordination complexes that mimic the structure/function of the MMO active site. One of these, a binuclear, coordinately-asymmetric copper complex, is capable of oxidizing cyclohexane to a mixture of cyclohexanol and cyclohexanone in the presence of hydrogen peroxide. DOE

PROMOTION OF GEOTHERMAL ENERGY DEVELOPMENT IN 1991 Survey Report No. 38
Jan. 1993 211 p In JAPANESE
(DE93-799061; ETDE/JP-MF-93799061) Avail: CASI HC A10/MF A03

The paper evaluates effects of geothermal energy exploration activities on the environment in the Mt. Aso west area. At survey points, H2S and SO2 are detected. Hg is 0.002-0.038 micro-g/cu m. Quality of river water is pure at each point. Most of the survey area is occupied by substitutional community like grassland, afforestation, etc. For geothermal development, it is necessary to pay attention to the protection of regions where natural vegitation is distributed and to make the deforestation area necessary and minimum. If the geothermal power plant is installed, it contributes further to the region in terms of employment and finance based on the development of the local industry. It is estimated that the five hot springs are formed by the heating of ground water, which originates as rain water, or by heating of the meteoric water which permeates the underground. For development, it is necessary to take measures to inject the output of the geothermal water into the deep underground. DOE

MULTICRYSTALLINE SILICON SOLAR CELLS: GETTERING OPTIMIZATION AND CHARACTERIZATION
W. K. Schubert 1993 6 p Presented at the 23rd Institute of Electrical and Electronics Engineers (IEEE) Photovoltaic Specialists Conference, Louisville, KY, 10-14 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-015001; SAND-92-2868C; CONF-930540-7) Avail: CASI HC A02/MF A01

Three multicrystalline silicon materials were used in preliminary experiments in preparation for a planned comprehensive gettering study on several industrial solar cell materials. Two processes commonly used to upgrade material quality were investigated: phosphorus gettering and aluminum-alloying. Microwave-detected photoconductance decay measurements of minority carrier lifetime and detailed analyses of full solar cells were used to determine the response to the gettering processes. Lateral nonuniformities were shown to be significant in these multicrystalline materials. Identification of the nature of the nonuniformities is important in developing an understanding of gettering effects. DOE

PROJECT AIRSTREAM: TRACE GAS Final Report
R. Leifer Dec. 1992 164 p
(DE93-008849; EML-549) Avail: CASI HC A08/MF A02

The results of 10 years of sampling for trace gases in the upper troposphere and lower stratosphere are presented. These samples were collected under the auspices of the Atomic Energy Commission (AEC), the Energy Research and Development Administration (ERDA), and the Department of Energy (DOE). Almost 1000 whole air samples were collected during the years 1973 to 1983 under Project AIRSTREAM. Project AIRSTREAM was part of the Environmental Measurements Laboratory's (EML, at that time called the Health and Safety Laboratory/HASL) research effort to investigate the impact of the injection of radionuclides and stable compounds into the stratosphere. One or more of the following compounds were analyzed: CCl3F, CCl2F2, CCl4, N2O, SF6, CO2, CH4, CH3CCl3, and COS. Details of the Project's quality assurance program are discussed. Also included in the report are two-dimensional plots of the concentration of CCl3F and a complete tabulation of the data. DOE

SOIL EROSION RATES CAUSED BY WIND AND SALTATING SAND STRESSES IN A WIND TUNNEL
M. W. Ligotke Feb. 1993 83 p
(Contract DE-AC06-76RL-01830)
(DE93-009154; PNL-8478) Avail: CASI HC A05/MF A01

Wind erosion tests were performed in a wind tunnel in support of the development of long-term protective barriers to cap stabilized waste sites at the Hanford Site. Controlled wind and saltating sand erosive stresses were applied to physical models of barrier surface layers to simulate worst-case eolian erosive stresses. The goal of these tests was to provide information useful to the design and evaluation of the surface layer composition of an arid-region waste site barrier concept that incorporates a deep fine-soil reservoir. A surface layer composition is needed that will form an armor resistant to eolian erosion during periods of extreme dry climatic conditions, especially when such conditions result in the elimination or reduction of vegetation by water deprivation or wildfire. Because of the life span required of Hanford waste barriers, it is important that additional work follow these wind tunnel studies. A modeling effort is planned to aid the interpretation of test results with respect to the suitability of pea gravel to protect the finite-soil reservoir during long periods of climatic stress. It is additionally recommended that wind tunnel tests be continued and field data be obtained at prototype or actual barrier sites. Results wig contribute to barrier design efforts and provide confidence in the design of long-term waste site caps for and regions. DOE

THE NORTH ATLANTIC REGIONAL EXPERIMENT (NARE)
P. Daum 22 Mar. 1993 4 p
(Contract DE-AC02-76CH-00016)
(DE93-010126; BNL-70309) Avail: CASI HC A01/MF A01 (US Sales Only)

A planning meeting for the North Atlantic Regional Experiment (NARE) summer 1993 field intensive was attended. The meeting was held at the University of East Anglia, Norwich, England from January 26--29, 1993. The meeting was organized by Stuart Penkett, and was attended by scientists from both North America and Europe. The summer intensive will be conducted during the month of August. Participating North American scientists will focus efforts on measurements along the northeastern coast of the US and in Nova Scotia. They will also support surface measurements in the Azores, Iceland, and in Bermuda. At least three instrumented aircraft will contribute to the North American effort. European activities will focus on the British Meteorological Office C-130 aircraft. The Europeans will also activate a number of existing sites to measure ozone concentration profiles. The coordination between measurements conducted on either side of the Atlantic will not be close because of the lack of meteorological data in the mid-Atlantic which would allow prediction of transoceanic transport. THE ROLE OF CLOUDS AND OCEANS IN GLOBAL GREENHOUSE WARMING
M. I. Hoffert Dec. 1992 21 p
(Contract DE-FG02-90ER-61014)
(DE93-016206; DOE/ER-61014/3) Avail: CASI HC A03/MF A01

During the past three years we have conducted several studies using models and a combination of satellite data, in situ meteorological and oceanic data, and paleoclimate reconstructions, under the DoE program, 'Quantifying the Link Between Change in Radiative Balance and Atmospheric Temperature.' Our goals were to investigate the effects of global cloudiness variations on global climate and their implications for cloud feedback and continue development and application of NYU transient climate/ocean models, with emphasis on coupled effects of greenhouse warming and feedbacks by both the clouds and oceans. Our original research plan emphasized the use of cloud, surface temperature, and ocean data sets interpreted by focused climate/ocean models to develop a cloud radiative forcing scenario for the past 100 years and to assess the transient climate response; to narrow key uncertainties in the system; and to identify those aspects of the climate system most likely to be affected by greenhouse warming over short, medium, and long time scales. DOE

THE FOOTPRINT AREA INFLUENCING A HIGH-VOLUME AIR SAMPLER
J. Shinn and F. Gouveia Oct. 1992 6 p
(Contract W-7405-eng-48)
(DE93-013947; UCRL-ID-112181) Avail: CASI HC A02/MF A01

A recent question posed by air sampling analysts is how to calculate the source area that contributes to the collection of material by a high-volume (HV) air sampler. In micrometeorology studies theoretical and numerical approaches have been used to determine the 'footprint' of an atmospheric flux from the ground that influences a sensor at any given height. Over the course of a few days or more, the influence of atmospheric stability on a high volume air sampler run can be neglected. For surfaces that have dense vegetative cover, the boundary layer is displaced upward by the vegetation height and the roughness is proportional to the vegetation height. It can be concluded that for typical surface conditions, the HV air sampler is 90% influenced by material flux from the surface less than 145-175 m upwind. For rougher surfaces, the upwind bounded distances are shorter. There may be some very specialized cases (e.g., empty parking lots) where the upwind bounded distances are much greater. DOE

DIAGNOSTIC STUDIES OF THE HxOy-NxOy-O3 PHOTOCHEMICAL SYSTEM USING DATA FROM NASA GTE FIELD EXPEDITIONS Final Report, 1 Jul. 1987 - 31 Jul. 1990
W. L. Chameides 7 Sep. 1990 6 p
(Grant NAG1-786)
(NASA-CR-193672; NAS 1.26:193672) Avail: CASI HC A02/MF A01

The research effort supported in part by the subject grant focused on three related topics. Our major effort was concentrated on the analysis of data gathered during GTE field expeditions. Ancillary efforts were directed at: the development and application of a Global Chemical Transport Model for the study of the atmospheric reactive nitrogen budget; the development and application of a one-dimensional, time dependent cloud model for the study of the impact of in-cloud aqueous phase chemistry on the atmospheric sulfur budget; and mechanistic studies of the chemical processes involved in dry deposition of ozone to vegetative surfaces. In the sections below, we briefly summarize the central conclusions of each of these efforts. These discussions are followed by a listing of the papers completed during

the granting period and the graduate students supported by funds from the grant. Reprints and preprints of all papers completed with support from the grant are attached as appendices. Author (revised)

MODELING OF BIOSPHERE-ATMOSPHERE INTERACTION FOR FOREST AND PASTURELAND IN THE AMAZON M.S. Thesis [MODELAGEM DA INTERACAO BIOSFERA-ATMOSFERA PARA AREAS DE FLORESTA E DE PASTAGEM NA AMAZONIA]
Humberto RibeirodaRocha May 1992 145 p In PORTUGESE
(INPE-5454-TDI/496) Avail: CASI HC A07/MF A02

Along the lines of the most recent studies of deforestation in the Amazon and its impact on the climate change, such as the decrease of the local evaporation (Wright et al., 1992), and the reduction of 20 percent in the regional rainfall (Nobre et al., 1991), the biosphere model SiB is calibrated for an Amazonian pastureland, and the bearing of surface vegetation in the boundary layer structure and in the development of convection in the atmospheric column is analyzed. A one-dimensional model is used to study the interaction of vegetation-atmosphere, having 18 layers in the vertical and parameterizations of surface, turbulent vertical diffusion, short and long waves radiation, deep and shallow convection, and large scale precipitation. A comparison is made between a control model (Ctr1D), which surface parameterization is based on the similarity laws of Monin and Obukhov (1954) and Penman-Monteith concept of evaporation, coupled to a 1st order turbulent closure model in the boundary layer, with a biosphere-coupled model (SiB1D), having SiB model at the surface and a 2nd order turbulent closure scheme (Mellor and Yamada, 1982). The 24 hours simulations of SiB1D appear to show more realistic sensible and latent heat fluxes at the surface, when admissing either forest or pastureland at the Amazon and comparing with observations. In addition, the numerical solution of SiB1D is more effective in suppressing some previous oscillations found in the Ctr1D model. Simulations of SiB1D model showed the convection in the atmospheric column to be stronger upon the forest either than the pasture, leading to an increase in the precipitation from 25 to 50 percent. The resulting effects are of heating the middle troposphere up to 2.5 K, and the moistening of the boundary layer up to 2.0 g/kg, both larger upon the forest. Author (revised)

AQUIS: A PC-BASED SOURCE INFORMATION MANAGER
A. E. Smith, C. C. Huber, J. Tschanz, and S. J. Ryckman, Jr. 1993 10 p Presented at the 86th Annual Meeting and Exhibition of the Air and Waste Management Association, Denver, CO, 13-18 Jun. 1993
(Contract W-31-109-eng-38)
(DE93-012893; ANL/EAIS/CP-78850; CONF-930647-3) Avail: CASI HC A02/MF A01

The Air Quality Utility Information System (AQUIS) was developed to calculate emissions and track them along with related information about sources, stacks, controls, and permits. The system runs on IBM-compatible personal computers with dBASE IV and tracks more than 1,200 data items distributed among various source categories. AQUIS is currently operating at 11 US Air Force facilities, which have up to 1,000 sources, and two headquarters. The system provides a flexible reporting capability that permits users who are unfamiliar with database structure to design and prepare reports containing user-specified information. In addition to the criteria pollutants, AQUIS calculates compound-specific emissions and allows users to enter their own emission estimates. DOE

OCEAN UPTAKE OF CARBON DIOXIDE
Tsung-Hung Peng and Taro Takahashi 1993 44 p Presented at the National Conference and Exposition on Heat Transfer, Atlanta, GA, 8-11 Aug. 1993
(Contract DE-AC05-84OR-21400)
(DE93-012967; CONF-930830-17) Avail: CASI HC A03/MF A01

Factors controlling the capacity of the ocean for taking up anthropogenic C02 include carbon chemistry, distribution of alkalinity, pCO2 and total concentration of dissolved C02, sea-air pCO2 difference, gas exchange rate across the sea-air interface, biological carbon pump, ocean water circulation and mixing, and dissolution of carbonate in deep sea sediments. A general review of these processes is given and models of ocean-atmosphere system based on our understanding of these regulating processes are used to estimate the magnitude of C02 uptake by the ocean. We conclude that the ocean can absorb up to 35 percent of the fossil fuel emission. Direct measurements show that 55 percent of C02 from fossil fuel burning remains in the atmosphere. The remaining 10 percent is not accounted for by atmospheric increases and ocean uptake. In addition, it is estimated that an amount equivalent to 30 percent of recent annual fossil fuel emissions is released into the atmosphere as a result of deforestation and farming. To balance global carbon budget, a sizable carbon sink besides the ocean is needed. Storage of carbon in terrestrial biosphere as a result of C02 fertilization is a potential candidate for such missing carbon sinks. DOE

POLLUTION PREVENTION THROUGH TOTAL QUALITY
D. L. Stoltz, M. G. Byrant, D. M. Eggers, R. W. Gough, and W. H. Schlosberg May 1993 16 p Presented at the 9th Waste Minimization and Pollution Prevention Conference, San Francisco, CA, 13-15 Apr. 1993
(Contract DE-AC04-76DP-00613)
(DE93-013814; KCP-613-5138; CONF-930483-7) Avail: CASI HC A03/MF A01

Application of Total Quality to AlliedSignal Inc., Kansas City Division's (KCD) Pollution Prevention Program has created a dynamic and focused effort to significantly reduce process inefficiencies and waste generation. KCD is demonstrating TQ's usefulness by empowering associates and obtaining their buy-in and ownership of pollution prevention principles. Specific pollution prevention working groups include: (1) establishing a comprehensive recycling process; (2) capitalizing on Environmentally Conscious Manufacturing (ECM) expertise; and (3) encouraging the internal implementation of ECM. TQ produces the performance results that promote and sustain plant-wide pollution prevention goals and activities. KCD uses AlliedSignall's nine step 'Process Improvement Problem/Solving Model' (Appendix A). Although this program only formally began within the past year, many of the tools have been used over the last eight years to achieve pollution prevention objectives. This paper focuses on the new attitude and gives examples of how each of the nine steps is being used in the KCD Pollution Prevention Program. This paper describes each step of the process and provides specific pollution prevention examples. DOE

The concept of planting trees as part of a strategy to confront the possibility of global climate change is now widely accepted. As trees grow they remove CO2 from the atmosphere and thus slow the atmospheric build-up of CO2, an important greenhouse gas. Within the global-climate-change context, there are two fundamental problems with managing trees to store carbon. First, the magnitude of fossil-fuel related emissions of CO2 is so large, 6 billion metric tons of carbon per year that it takes very large areas of tree planting to make a significant impact. Second, as trees mature their rate of growth, and hence rate of net carbon uptake, declines. The large demand on land area suggests that there is a limit to the fraction of total CO2 emissions that we might reasonably expect to offset with growing trees. The ultimate maturation of

forests suggests that there is a limit on the length of time over which offsets are feasible and that we need to ask what to do as the rate of C uptake declines. Acknowledging that the availability of land will constrain the ability of tree planting to offset industrial emissions of CO2, we consider how the land which is available can be used most effectively. This report speculates on how much land might be available for a forest management strategy motivated (at least partially) by concerns about climate change, but our principal focus is on how a given land area can be best used to minimize net emissions of CO2 and how much might be achieved on a unit of land. We do not suggest that carbon management should be the principal criteria for land management, but we discuss the implications if it were. Confronting global and local changes in climate will be one of many objectives in land management and we explore for the most effective strategy for pursuing this objective. DOE

AN EXAMINATION OF UTILITY EMISSIONS CONTRIBUTIONS TO ELEVATED OZONE CONCENTRATIONS IN THE CHICAGO AREA

M. E. Fernau, K. A. Guziel, and D. W. South 1993 11 p Presented at the 86th Annual Meeting and Exhibition of the Air and Waste Management Association, Denver, CO, 13-18 Jun. 1993

(Contract W-31-109-eng-38)

(DE93-012852; ANL/EAIS/CP-78927; CONF-930647-2) Avail: CASI HC A03/MF A01

In order to reduce the pollutant load to the atmosphere and subsequent damaging effects, Titles 1 and 4 of the Clean Air Act Amendments of 1990 (CAAA's) require reductions in emissions of sulfur dioxide (SO2), nitrogen oxides (NO(x)), and volatile organic compounds (VOC's). Title 4 is aimed at reducing acidic deposition and requires utilities to reduce SO(2) and NO(x) emissions to specified levels. As a consequence of this, many utilities will have to install SO2 and NO(x) control technologies. Title 1 is concerned with bringing regions into compliance with the National Ambient Air Quality Standards (NAAQS) for the criteria pollutants, among which is ozone (O3). The NAAQS for O3 is 120 ppb (parts per billion by volume) hourly average concentration, not to be exceeded four times in three years. O3 is a secondary pollutant formed in the atmosphere when NO(x) and VOC's react together in the presence of sunlight. Utilities are a significant source of NO(x) and an unimportant source of VOC's. In the past, O3 control strategy has focused on reducing VOC emissions because of the possibility that reducing NO(x) actually might make O3 concentrations higher. However, this approach has not worked, perhaps because of underestimation of natural and manmade VOC emissions and transport of O3 from other regions. Computer modeling has shown that for many highly polluted areas massive NO(x) reductions may be necessary in addition to or in place of VOC controls. Utilities are a potential source of these NO(x) reductions. DOE

STABILITY OF REFERENCE MASSES 1: EVIDENCE FOR POSIIBLE VARIATIONS IN THE MASS OF REFERENCE KILOGRAMS ARISING FROM MERCURY CONTAMINATION

P. J. Cumpson and M. P. Seah Jan. 1993 16 p

(NPL-DMM(A)-86; ETN-93-94461) Copyright Avail: National Physical Laboratory, Teddington, Middlesex TW11 OLW, United Kingdom HC

Samples of Pt/10 percent Ir were studied by X-ray Photoelectron Spectroscopy (XPS) to assess environmental contamination of reference kilogram masses. Samples were sputtered clean and distributed to four places where reference kilograms are kept. All four specimens showed carbon and oxygen contamination. All four specimens additionally showed mercury contamination, with levels that varied from venue to venue. Of all metals, mercury has the highest vapor pressure, is commonly used in laboratories, and reacts with platinum; in hindsight the results are not surprising. The worst venue, wherein the reference kilogram had an effective mass increase of 0.26 micrograms of mercury/day, was the case enclosing the UK primary balance. The mercury is not removed by washing or by scrubbing with a chamois leather soaked in ethanol and ether. The mercury level is therefore probably stable after a period following manufacture, unless the mass is exposed to a venue with a higher mercury level. It is recommended that in relation to Pt or Pt/Ir masses all equipment containing mercury be removed from weighing laboratories, venues be monitored for mercury by XPS, and further work be done to determine whether best mass stability would be achieved by controlled mercury saturation after the reference mass is made, or by storage in a rigorously contaminant free environment. ESTIMATION OF THE CONCENTRATION VERSUS THE TIME PROFILE OF ZINC CHLORIDE PARTICLES IN SMOKE CLOUDS GENERATED BY THE RAUFOSS A/S INSTANTANEOUS SMOKE RA-90 AND DM-45 HC SMOKE GENERATOR

Jan H. Blanch 10 Feb. 1993 12 p

(FFI-93/6001; ETN-93-94453) Avail: CASI HC A03/MF A01

Possible hazards that may arise from the outdoor use of two smoke generating devices, specifically the DM-45 HC smoke generator and the recently developed RA-90 instantaneous smoke concept, are investigated. To accomplish such a task, it is necessary to know the concentration versus time profiles of the most hazardous compound in the smoke clouds generated by these devices. The concentration of zinc chloride in clouds generated by RA-90 and DM-45 in two typical weather situations is estimated. The DM-45 HC smoke generator produces smoke with markedly higher maximum concentrations of zinc chloride particles than the RA-90 instantaneous smoke concept. The maximum time personnel may be exposed to the highest zinc chloride concentrations is also markedly longer for the DM-45. ESA

An account of the third in the series of environmental radioactivity measurement intercomparison exercises is given. Two sets of samples were prepared, one containing alpha emitters and one containing beta and beta/gamma emitters. The participants fell into three groups: the nuclear industry and the statutory monitoring organizations, organizations with a secondary interest in the nuclear industry (such as water companies) and contract laboratories. The results for this exercise are reported. In general, the results are satisfactory and the level of performance is comparable to previous years. ESA

SPATIAL AND TEMPORAL VARIABILITY OF PRECIPITATION AND CHEMISTRY: CASE STUDIES FROM THE FRONTAL BOUNDARY STUDY

M. T. Dana Jan. 1993 7 p Presented at the 73rd American Meteorological Society Annual Meeting, Anaheim, CA, 17-22 Jan. 1993

(Contract DE-AC06-76RL-01830)

(DE93-007883; PNL-SA-21492; CONF-930133-10) Avail: CASI HC A02/MF A01

Regional and larger-scale models of pollutant transport and deposition generally, by practical necessity, must be limited in output of precipitation rate and chemical composition to values for selected time intervals representing areas on the order of 10(exp 4) sq km. Naturally, it is of some concern that these values be reasonably representative of natural variations both in time and space. This question may be approached through field studies involving detailed spatial (using a network of samplers on the model grid scale) and temporal (using sequential sampling) measurements. This paper presents an initial analysis, using simple statistical concepts, of data bases from such a field study, the Frontal Boundary Study (FBS). DOE

BINARY HOMOGENEOUS NUCLEATION: TEMPERATURE AND RELATIVE HUMIDITY FLUCTUATIONS AND NON-LINEARITY
R. C. Easter and L. K. Peters (Kentucky Univ., Lexington.) Jan. 1993 9 p Presented at the 73rd American Meteorological Society Annual Meeting, Anaheim, CA, 17-22 Jan. 1993
(Contract DE-AC06-76RL-01830)
(DE93-007884; PNL-SA-21486; CONF-930133-9) Avail: CASI HC A02/MF A01

This report discusses binary homogeneous nucleation involving H2SO4 and water vapor, which is thought to be the primary mechanism for new particle formation in the marine boundary layer. The temperature, relative humidity, and partial pressure of H2SO4 vapor are the most important parameters in fixing the binary homogeneous nucleation rate in the H2SO4/H2O system. The combination of thermodynamic calculations and laboratory experiments indicates that this rate varies roughly as the tenth power of the saturation ratio of H2SO4 vapor. Furthermore, the vapor pressure of H2SO4 is a function of temperature, and similar dependencies of the binary homogeneous nucleation rate on relative humidity can be noted as well. These factors thus introduce strong non-linearities into the system, and fluctuations of temperature, relative humidity, and H2SO4 vapor concentrations about mean values may strongly influence the nucleation rate measured in the atmosphere. THE ROLE OF HUMAN ACTIVITY AND LAND USE CHANGE IN ATMOSPHERIC CHEMISTRY AND AIR QUALITY
J. E. Penner Jul. 1992 45 p Presented at the SNOWMASS Meeting, Denver, CO, 21 Jul. - 10 Aug. 1991
(Contract W-7405-eng-48)
(DE93-011871; UCRL-JC-110922; CONF-9107235-1) Avail: CASI HC A03/MF A01

In the this paper, I review the importance of several fossil fuel combustion byproducts in terms of atmospheric chemistry, air quality, and climate. I then review current estimates of the sources for each specie, deriving the fraction of each source that is due to specific land use practices or land cover categories. Understanding the current trends of those species with known increasing abundances and projecting increases into the future is possible if the estimated sources from human activity and land use change can be projected and if the known atmospheric sinks and the interactions in atmospheric chemistry and climate change are appropriately taken into account. Regional trends in the short-lived species can be projected as well, assuming the estimated sources and sinks are correct. However, significant uncertainties continue to surround the estimated budgets for most of these species. Uncertainties and the estimated ranges in different source strength estimates for each are also discussed. DOE

BIODIESEL/AQUATIC SPECIES PROJECT REPORT, FY 1992
L. Brown, E. Jarvis, T. Dunahay, P. Roessler, K. Zeiler, and S. Sprague (Department of Energy, Washington, DC.) May 1993 33 p
(Contract DE-AC02-83CH-10093)
(DE93-010024; NREL/TP-422-5259) Avail: CASI HC A03/MF A01

The primary goal of the Biodiesel/Aquatic Species Project is to develop the technology for growing microalgae as a renewable biomass feedstock for the production of a diesel fuel substitute (biodiesel), thereby reducing the need for imported petroleum. Microalgae are of interest as a feedstock because of their high growth rates and tolerance to varying environmental conditions, and because the oils (lipids) they produce can be extracted and converted to substitute petroleum fuels such as biodiesel. Microalgae can be grown in arid and semi-arid regions with poor soil quality, and saline water from aquifers or the ocean can be used for growing microalgae. Biodiesel is an extremely attractive candidate to fulfill the need for a diesel fuel substitute. Biodiesel is a cleaner fuel than petroleum diesel; it is virtually free of sulfur, and emissions of hydrocarbons, carbon monoxide, and particulates during combustion are significantly reduced in comparison to emissions from petroleum diesel. Biodiesel provides essentially the same energy content and power output as petroleum-based diesel fuel. DOE

SYNTHESIS INVERSION OF ATMOSPHERIC CO2 USING THE GISS TRACER TRANSPORT MODEL
I. G. Enting, C. M. Trudinger, R. J. Francey, and H. Granek 1993 47 p
(CSIRO-TP-29; ISBN-0-643-05251-8) Copyright Avail: Issuing Activity

The atmospheric CO2 budget for the period around 1986-1987 is estimated using a Bayesian synthesis analysis. The source strengths of a set of industrial, biotic, and ocean processes are estimated by matching observed concentrations to modeled concentrations calculated using the GISS three-dimensional tracer transport model. The Bayesian synthesis uses prior estimates of these process strengths to stabilize what is otherwise an ill-conditioned inversion. The analysis gives preliminary estimates of the ranges of uncertainty arising from the inversion. The inversion uses observations of the concentration and delta(13)C of atmospheric CO2. The ability to estimate uncertainties makes it possible to compare the relative importance of various data items in reducing these uncertainties. The main result is that global totals of oceanic versus biotic exchange are determined primarily by the combined global budgets for CO2 and (13)CO2. The atmospheric transport model constrains the regional sources and sinks but these constraints make only a small contribution to reducing the uncertainty in the global budget. Our best estimate of the global net air-sea carbon flux is 1.4 +/- 1.0 Gt C/y. The net carbon storage by the oceans will be some 0.6 Gt C/y greater than this CO2 flux due to carbon transported into the oceans by rivers. The corresponding estimate of air-to-biota CO2 flux is -2.5 +/- 0.9 Gt C/y implying a net storage of -1.3 Gt C/y after accounting for carbon lost from the biota via rivers or as CO. We find that within the range of approximately I Gt C/y our estimate of air-sea flux is very sensitive to the choice of data that are fitted. This confirms the appropriateness of our formal error estimates that are based on a priori statistics. These large uncertainties mean that our budget estimates must be regarded as preliminary and indicate the need for a refined statistical analysis of the observational data to assess their representativeness. A simple preliminary study of oxygen distributions is presented. The results indicate that, once the CO2 distribution is fitted, the spatial gradient of oxygen does not give significant additional discrimination between alternative carbon budgets and that the long-term trend of atmospheric oxygen will make the greatest contribution to resolving carbon budgets.

DESTRUCTION OF PROBLEMATIC AIRBORNE CONTAMINANTS BY HYDROGEN REDUCTION USING A CATALYTICALLY ACTIVE, REGENERABLE SORBENT (CARS) Final Report
John O. Thompson and James R. Akse Jul. 1993 52 p
(Contract NAS2-13714)
(NASA-CR-194354; NAS 1.26:194354; URC-80436) Avail: CASI HC A04/MF A01

Thermally regenerable sorbent beds were demonstrated to be a highly efficient means for removal of toxic airborne trace organic contaminants aboard spacecraft. The utilization of the intrinsic weight savings available through this technology was not realized since many of the contaminants desorbed during thermal regeneration are poisons to the catalytic oxidizer or form highly toxic oxidation by-products in the Trace Contaminant Control System (TCCS). Included in this class of compounds are nitrogen, sulfur, silicon, and halogen containing organics. The catalytic reduction of these problematic contaminants using hydrogen at low temperatures (200-300 C)

offers an attractive route for their destruction since the by-products of such reactions, hydrocarbons and inorganic gases, are easily removed by existing technology. In addition, the catalytic oxidizer can be operated more efficiently due to the absence of potential poisons, and any posttreatment beds can be reduced in size. The incorporation of the catalyst within the sorbent bed further improves the system's efficiency. The demonstration of this technology provides the basis for an efficient regenerable TCCS for future NASA missions and can be used in more conventional settings to efficiently remove environmental pollutants.

PROGRAM OPERATIONS PLAN
Apr. 1993 105 p
(DE93-012765; DOE/ER-0586T) Avail: CASI HC A06/MF A02

The Department of Energy's Atmospheric Chemistry Program (ACP) was initiated in 1991 to coordinate DOE's university and federal-laboratory atmospheric-chemistry research and to focus these efforts on national and international information requirements in the atmospheric-chemistry field. This Program Operations Plan describes the structure and vision of the effort designed to fulfill these needs, and is divided into two major components. The first of these is a Strategic Plan, which outlines the ACP's rationale, objectives, and vision, and describes its products that are anticipated over a future ten-year period. Although based on realistic appraisals of goals that are attainable given the financial, material, and intellectual resources of the ACP community, this Strategic Plan does not describe these resources themselves. The second component of the Program Operations Plan, the Implementation Plan, deals directly with these resource considerations. As such it focuses on practical implementation of Strategic-Plan elements at the individual research institutions, the anticipated scientific contributions of these groups, and their coordination within the ACP. In contrast to the Strategic Plan, this Implementation Plan extends only five years into the future. DOE

A LASER-BASED TECHNIQUE TO CONTINUOUSLY MONITOR METAL AEROSOL EMISSIONS
W. L. Flower, L. W. Peng, N. B. French, H. A. Johnsen, D. K. Ottesen, R. F. Renzi, and M. P. Bonin 1993 19 p Presented at the EPRI Workshop, Scottsdale, AZ, 19-22 May 1993
(Contract DE-AC04-76DR-00789)
(DE93-012836; SAND-93-8558C; CONF-9305183-1) Avail: CASI HC A03/MF A01

Sandia National Laboratories is developing an instrument to continuously monitor metal aerosol emissions. Applications for this monitor range from industrial process vents (e.g., exhaust stacks from electroplating baths) to waste treatment processes (incinerators), to boilers and industrial furnaces (coal-fired power plants). The monitoring technique is based on Laser Spark Spectroscopy ((LASS) also known as Laser-Induced Breakdown Spectroscopy--LIBS), in which a pulsed laser is used to rapidly heat a particle and produce a plasma (or laser 'spark'). The light emission from the spark is spectrally resolved and analyzed to identify the elemental constituents of the particle and quantify the abundance of the measured species. One feature of LASS is that it can measure atomic species embedded in either solid particles or fine liquid droplets, which account for a large percentage of metal emissions from applications of interest. Presented here are a description of the technique and initial results from laboratory simulations to determine sensitivity and to establish calibration procedures. Our project is currently focused on measuring chromium emissions from electroplating baths. This work forms the basis for future applications to incineration and fossil power plants since chromium is one of the more toxic metals under regulation by the Clean Air Act. DOE

LONG-RANGE GLOBAL WARMING IMPACT OF GASEOUS DIFFUSION PLANT OPERATION
L. D. Trowbridge Sep. 1992 40 p
(Contract DE-AC05-84OT-21400)
(DE93-011686; K/ETO-112) Avail: CASI HC A03/MF A01

The DOE gaseous diffusion plant complex makes extensive use of CFC-114 as a primary coolant. As this material is on the Montreal Protocol list of materials scheduled for production curtailment, a substitute must be found. In addition to physical cooling properties, the gaseous diffusion application imposes the unique requirement of chemical inertness to fluorinating agents. This has narrowed the selection of a near-term substitute to two fully fluorinated material, FC-318 and FC-3110, which are likely to be strong, long-lived greenhouse gases. In this document, calculations are presented showing, for a number of plausible scenarios of diffusion plant operation and coolant replacement strategy, the future course of coolant use, greenhouse gas emissions (including coolant and power-related indirect CO2 emissions), and the consequent global temperature impacts of these scenarios. TOXIC SUBSTANCES CONTROL ACT (TSCA) CHEMICAL SUBSTANCES INVENTORY: REVISED INVENTORY SYNONYM AND PREFERRED NAME FILE, JAN. 1993 DOCUMENTATION
Jan. 1993 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-155166) Avail: CASI HC A03

The computer-readable TSCA Chemical Substance Inventory is issued periodically to provide chemical substance information for those substances on the non-confidential substance identity portion of the TSCA Master Inventory File. For a complete understanding of the data contained on these tapes, it is necessary to consult the introductory material of the printed 1985 Edition and the 1990 Supplement to 1985 Edition. These tapes contain no TSCA Confidential Business Information. They have been prepared by Chemical Abstracts Service, a Division of the American Chemical Society, under contract to the U.S. Environmental Protection Agency. The tapes consist of two files: Inventory Preferred Name File and Inventory Synonym Name File. The first file contains the CAS Registry Number, preferred CA Index Name, molecular formula, and other appropriate information for each non-confidential inventory chemical substance. The entries are in ascending CAS Registry Number order. The second file is a file of synonymous chemical names for the same substances listed in the Preferred Name File. Its entries are ordered alphabetically by name with each name accompanied by the same information for the substances as appears in the Preferred Name File. Author

Andreas Koetz 1991 156 p In GERMAN
(Mitt-81; ETN-93-94383) Avail: CASI HC A08/MF A02

Effects of aerosol phase in sulfate-nitrate-ammonium system on long range transport and deposition of sulfur and nitrogen in the troposphere are examined. Aerosol MARS (Model for an Aerosol Reacting System), which is based on thermodynamic concepts and allows aerosol composition to be calculated from relative humidity, sulfate formation rate in the gaseous phase and ammoniac and nitric acid concentrations, is described. Data about nitrogen and sulfur oxide emissions in Europe are presented using spatial distribution curves. A unidimensional model, which involves chemical reactions, emissions, deposition and vertical diffusion, was used for description of daily transport and vertical distribution of aerosol species; interactions between gaseous phase and sprays were considered as relaxation to the concentrations given by the thermodynamic equilibrium between both phases. Numerical spreading simulations were carried out with the three dimensional Euler model CTM2 (Chemistry Transport Model), derived from regional acid deposition model, in order to depict chemical transformations, and dry and wet deposition of trace particles in the troposphere. MEASURING SURFACE FLUXES IN CAPE Final Report, 23 Apr. 1991 - 22 Apr. 1992
E. T. Kanemasu, T. D-Shah, and Dalin Nie 1992 7 p
(Grant NAG8-880)
(NASA-CR-193664; NAS 1.26:193664) Avail: CASI HC A02/MF A01

Two stations (site 1612 and site 2008) were operated by the University of Georgia group from 6 July 1991 to 18 August 1991. The following data were collected continuously: surface energy fluxes (i.e., net radiation, soil heat fluxes, sensible heat flux and latent heat flux), air temperature, vapor pressure, soil temperature (at 1 cm depth), and precipitation. Canopy reflectance and light interception data were taken three times at each site between 6 July and 18 August. Soil moisture content was measured twice at each site. Author (revised)

NATIONAL ATMOSPHERIC SCIENCES PROGRAM, FISCAL YEARS 1987-1990
24 Aug. 1992 142 p
(NSF-92-16) Avail: CASI HC A06/MF A02

This report describes the atmospheric sciences research programs of the SAR member agencies for Fiscal Years 1987-1990 with accompanying

fiscal data for those years. In addition there are appendices that include information on national and international atmospheric research and environmental organizations. Budgetary information also is presented for the U.S. Global Change Research Program (FY 1989 and 1990), for the National Acid Precipitation Assessment Program and the National Climate Program (FY 1987 through 1990). It is the latest in an ongoing series of reports which satisfy the responsibility for reviews of Federal R&D programs in the Earth Sciences as required by the FCCSET/CEES.

Aberdeen Proving Ground (APG) is currently managing a comprehensive Installation Restoration Program involving more than 360 solid-waste managing units contained within 13 study areas. The Edgewood area and two landfills in the Aberdeen area appear on the National Priority List under the Comprehensive Environmental Response, Compensation, and Liability Act. Therefore, APG has entered into an interagency agreement with the US Environmental Protection Agency to address the listed areas. The West Branch of the Canal Creek area, located within the Edgewood area, is one of the areas that requires a Source Definition Study because there is an ongoing release of volatile organic compounds into the creek. A report prepared in 1989 included a list of 29 potentially contaminated buildings in the Edgewood area. Sixteen of the buildings contain known contaminants, nine buildings contain unknown contaminants, and four of the buildings are potentially clean. The EAI report recommended that a sampling and monitoring program be established to verify contamination levels in and around each building. Thirteen of the potentially contaminated buildings are in the West Branch of the Canal Creek area and are potential sources of volatile organic compounds. Operations have ceased, and the buildings have been abandoned, but processing equipment, sumps, drains, ventilation systems, and underground storage tanks remain. These appurtenances may contain liquid, solid, or vapor contaminants of unknown nature. DOE

ION ANISOTROPY DRIVEN WAVES IN THE EARTH'S MAGNETOSHEATH AND PLASMA DEPLETION LAYER
R. E. Denton, M. K. Hudson (Dartmouth Coll., Hanover, NH.), B. J. Anderson (Johns Hopkins Univ., Laurel, MD.), and S. A. Fuselier (Lockheed Aircraft Corp., Palo Alto, CA.) 1993 17 p Presented at the AGU Monograph/Solar System Plasma Physics Meeting on Resolution of Processes in Space and Time, Yosemite, CA, Feb. 1993
(Contract W-7405-eng-36)
(DE93-012751; LA-UR-93-1470; CONF-9302115-3) Avail: CASI HC A03/MF A01

Recent studies of low frequency waves (omega(sub r) less than omega(sub p), where omega(sub p) is the proton gyrofrequency) observed by AMPTE/CCE in the plasma depletion layer and magnetosheath proper are reviewed. These waves are shown to be well identified with ion cyclotron and mirror mode waves. By statistically analyzing the transitions between the magnetopause and time intervals with ion cyclotron and mirror mode waves, it is established that the regions in which ion cyclotron waves occur are between the magnetopause and the regions where the mirror mode is observed. This result is shown to follow from the fact that the wave spectral properties are ordered with respect to the proton parallel beta, (beta)(sub (parallel)p). The later result is predicted by linear Vlasov theory using a simple model for the magnetosheath and plasma depletion layer. Thus, the observed spectral type can be associated with relative distance from the magnetopause. The anisotropy-beta relation, A(sub p) triple bond (T(perpendicular)/T(sub parallel))(sub p) - 1 = 0.50(beta)(sub (parallel)p)(sup -0.48) results from the fact that the waves pitch angle scatter the particles so that the plasma is near marginal stability and is a fundamental constraint on the plasma. DETERMINATION OF SPECTROSCOPIC PROPERTIES OF ATMOSPHERIC MOLECULES FROM HIGH RESOLUTION VACUUM ULTRAVIOLET CROSS SECTION AND WAVELENGTH MEASUREMENTS Semiannual Status Report No. 17, 1 Nov. 1992 - 30 Apr. 1993
W. H. Parkinson, K. Yoshino, and D. E. Freeman Jul. 1993 13 p
(Grant NAG5-484)
(NASA-CR-194024; NAS 1.26:194024) Avail: CASI HC A03/MF A01

An account is given of progress during the six-month period 1 Nov. 1992 to 30 Apr. 1993 on work on (1) cross section measurements of the Schumann-Runge continuum; (2) the determination of the predissociation linewidths of the Schumann-Runge bands of O2; (3) the determination of the molecular constants of the ground state of O2; (4) cross section measurements of CO2 in wavelength region 120-170 nm; and (4) determination of dissociation energy of O2. The experimental investigations are effected at high resolution with a 6.65 m scanning spectrometer which is, by virtue of its small instrumental width (FWHM = 0.0013 nm), uniquely suitable for cross section measurements of molecular bands with discrete rotational structure. Below 175 nm and in the region of the S-R continuum, synchrotron radiation is suitable for cross section measurements. All of these spectroscopic measurements are needed for accurate calculations of the production of atomic oxygen and penetration of solar radiation into the Earth's atmosphere. Author (revised)

ATMOSPHERIC SOUNDINGS DURING THE WASHITA 1992 CAMPAIGN Final Technical Report, 1 Jun. - 30 Sep. 1992
W. Brutsaert 30 Sep. 1992 10 p
(Grant NAG5-1989)
(NASA-CR-194383; NAS 1.26:194383) Avail: CASI HC A02/MF A01

During the period June 9 through June 18, 1992, an intensive radiosounding program was conducted to measure atmospheric profiles of the wind velocity, the temperature and the specific humidity. The launch site was located near site MS000 in the northeastern part of the catchment of the Little Washita River; this location was selected in order to ensure that the measured profiles would reflect the catchment's surface features for the prevailing southwesterly winds during this time of the year. The launch times of the rawinsondes are shown. Derived from text

ELECTRODYNAMICS OF THE MIDDLE ATMOSPHERE: SUPERPRESSURE BALLOON PROGRAM Final Report, 15 Apr. 1986 - 30 Jun. 1990; Abstract Only
Robert H. Holzworth 28 Aug. 1990 1 p
(Grants NAG5-635; NAGw-724; NSF ATM-80-17071; NSF ATM-82-12283; NSF ATM-84-11326; NSF ATM-86-15628)
(NASA-CR-193671; NAS 1.26:193671) Avail: CASI HC A01/MF A01

This project called Electrodynamics of the Middle Atmosphere (EMA): Superpressure Balloon Program was begun by the PI at the Aerospace Corporation in Los Angeles under joint NSF and NASA funding originally combined in one grant ATM80-17071 and has continued at the University of Washington under grants ATM8212283, ATM84-11326 and ATM86-15628 and NASA grants NAGW-724 and NAGS-635. In the EMA experiment a comprehensive set of electrical parameters was measured during eight long-duration balloon flights in the Southern Hemisphere stratosphere. These flights resulted in the largest vector electric field data set ever collected from the stratosphere which has been a treasure-trove of new phenomena. Since the stratosphere has never been electrodynamically sampled in this systematic manner before, it is perhaps not surprising that several new discoveries have been made and reported. Another way to measure the success of this first EMA project is to note that all together the total data rate was about 1 bit/sec/payload amounting to 12 MBytes (1/3 of 1 standard 1600 BPI magnetic tape) which nevertheless has resulted in 14 papers and 2 masters theses (so far! . Ten of these papers and one masters thesis specifically acknowledge the support by NASA grant NAGS-635 are discussed herein. Author

THE 1990 WESTERN PACIFIC GEOPHYSICS MEETING
1990 57 p Meeting was held in Kanazawa, Japan, 15-21 Aug. 1990

(Grant NAGw-2821)
(NASA-CR-193456; NAS 1.26:193456) Avail: CASI HC A04/MF A01

The 1990 Western Pacific Geophysics Meeting was held in Kanazawa, Japan from 15-21 Aug. 1990. This was the first meeting of a new series of meetings for the American Geophysical Union, and it proved to be very successful in terms of the scientific program and attendance, which included over 1,000 participants. The intent of this meeting was an effort on the part of the American Geophysical Union (AGU) and several Japanese geophysical societies to gather individual Earth and space scientists at a major scientific meeting to focus on geophysical problems being studied in the western Pacific rim. The meeting was organized along the lines of a typical AGU annual meeting with some invited talks, many contributed talks, poster sessions, and with emphasis on presentations and informal discussions. The program committee consisted of scientists from both the U.S. and Japan. This meeting provided ample opportunities for U.S. and Japanese scientists to get to know each other and their works on a one-to-one basis. It was also a valuable opportunity for students studying geophysics to get together and interact with each other and with scientists from both the U.S. and Japan. There were 939 abstracts submitted to the conference and a total of 102 sessions designed as a result of the abstracts received. The topics of interest are as follows: space geodetic and observatory measurements for earthquake and tectonic studies; gravity, sea level, and vertical motion; variations in earth rotation and earth dynamics; sedimentary magnetism; global processes and precipitation; subsurface contaminant transport; U.S. Western Pacific Rim initiatives in hydrology; shelf and coastal circulation; tectonics, magmatism, and hydrothermal processes; earthquake prediction and hazard assessment; seismic wave propagation in realistic media; and dynamics and structure of plate boundaries and of the Earth's deep interior. THE AMERICAN GEOPHYSICAL UNION CHAPMAN CONFERENCE ON TECTONICS AND TOPOGRAPHY
1992 42 p Conference was held in Snowbird, UT, 31 Aug. - 4 Sep. 1992
(Grant NAGw-3089)
(NASA-CR-193454; NAS 1.26:193454) Avail: CASI HC A03/MF A01

The Chapman Conference on Tectonics and Topography was held 31 Aug. - 4 Sep. 1992. The conference was designed to bring together disparate groups of earth scientists who increasingly found themselves working on similar problems but in relative isolation. Thus, process geomorphologists found themselves face-to-face with numerical modelers and field geomorphologists, hydrologists encountered geologists, and tectonophysicists found people with related data. The keynote speakers represented a wide variety of disciplines, all of which were relevant to the interdisciplinary theme of the conference. One of the most surprising issues that surfaced was the relative dearth of data that exists about erosion--process and rates. This was exacerbated by a reminder that erosion is critical to the evaluation of surface uplift. Author (revised)

GRAVITY AS A PROBE FOR UNDERSTANDING PATTERN SPECIFICATION Final Technical Report
George M. Malacinski and Anton W. Neff 28 Aug. 1993 9 p
(Grant NAGw-1548)
(NASA-CR-194142; NAS 1.26:194142) Avail: CASI HC A02/MF A01

Amphibian eggs from Xenopus laevis were employed as a model system. Xenopus embryos were demonstrated to be sensitive to novel force fields. Under clinostat-simulated weightlessness the location of the third cleavage furrow was shifted towards the equator; the dorsal lip was shifted closer to the vegetal pole; and head and eye dimensions of hatching tadpoles were enlarged. Effects of centrifuge-simulated hypergravity were the opposite of those of simulated weightlessness. Those morphological alterations had their own force-sensitive period, and a substantial spawning-to-spawning variation in sensitivity was observed. Despite those dramatic differences in embryogenesis, tadpoles at the feeding stage were largely indistinguishable from controls. Derived from text

THEORETICAL SUPPORT FOR THE AIRBORNE ANTARCTIC OZONE EXPERIMENT Final Report
Dennis L. Hartmann 3 Mar. 199
(Grant NAGw-1160)
(NASA-CR-193669; NAS 1.26:193669) Avail: CASI HC A01/MF A01

This investigation was to provide theoretical support during and after the deployment of NASA research aircraft to Punta Arenas, Chile during August and September of 1987 to conduct the Airborne Antarctic Ozone Experiment. The experiment was very successful in demonstrating the role of anthropogenic chlorine in producing the ozone hole over Antarctica during September and October of 1987. The PI worked primarily on using tracer data from the ER-2 aircraft to show that transport could not have caused the ozone hole in 1987, and that transport of chemical species into the polar vortex was very weak during the period of the experiment. The presence of gravity waves was also very apparent in the ER-2 data, and papers were published on this analysis and on the use of meteorological analyses to position the aircraft within the vortex. MINIMAL MODELING OF THE BIMODALITY OF EXTRATROPICAL ATMOSPHERIC PLANETARY WAVES Ph.D. Thesis
Lionel Pandolfo 1992 294 p
Avail: Univ. Microfilms Order No. DA9308997

Recent analyses of atmospheric data have indicated that the amplitude of atmospheric waves of planetary scale can switch from a mode of large amplitudes to a mode of small ones and vice versa. This behavior is present in both, the Northern and Southern Hemispheres. These observations are described and situated in the context of low frequency, intraseasonal variability. Most theories of bimodality rely on the presence of an extratropical source of long Rossby waves and on their interaction with the forcing in order to achieve a resonance in the response of the planetary flow. The incompatibility of these theories with the observations characterizing global weather regimes is demonstrated. Then, a hierarchy of numerical, quasi-geostrophic models are developed in order to determine the simplest model containing the minimal physics sufficient for generating bimodal statistics for the planetary waves. The physical properties which allow the production of bimodal dynamics relate to the stability characteristics of the models' stationary solutions and to the tonal wavenumber(s) at which the lower boundary is felt. The latter is not a major catalyst for the appearance of dynamical instabilities in spectral models retaining a large number of components in the truncation, contrary to the results from low-order ones. Instabilities and bimodality appear in our model when it is run with no lower-boundary forcing. Asymmetries in the latter actually supply a phase-locking mechanism favoring the establishment of standing oscillations. The validity of models with channel geometry was questioned on the ground that they would allow for resonant behavior by preventing latitudinal wave propagation. The problem of the dispersion of perturbation energy across parallels of latitude from a source embedded in a fluctuating zonal-mean flow, using a linearized, non-divergent barotropic vorticity equation and a basic zonal-mean flow constructed from atmospheric data were studied. It was found that the spatial fluctuations of the basic tonal flow can offer a localizing mechanism that acts to confine wave propagation to a certain latitude band around the source of perturbation energy. The critical parameters characterizing the wave as propagating or confined consist of the amplitude and meridional scale of the fluctuations. Dissert. Abstr.

NUMERICAL SIMULATION AND PARAMETERIZATION OF OROGRAPHIC GRAVITY WAVES Ph.D. Thesis
Young-Joon Kim 1992 283 p
Avail: Univ. Microfilms Order No. DA9310877

The problem of parameterizing gravity waves generated by subgrid-scale orography has recently been recognized important for large-scale models of the atmosphere. It was pointed out, for example, that excessively strong

westerlies may appear in the mid-latitude Northern Hemisphere winter if subgrid-scale orographic gravity-wave drag is neglected in high-resolution simulations. To date, parameterization schemes for orographic gravity waves were evaluated only on merits of overall improvement of simulated large-scale fields. A direct way of assessing parameterization schemes by using a numerical mesoscale gravity-wave model is followed: regarding a subdomain of the mesoscale model as a horizontal grid interval of a large-scale model, two vertical drag profiles - one estimated from a parameterization scheme applied to the subdomain-averaged variables and the other calculated directly from the variables at individual grid points of the mesoscale model - are compared. As a preparatory step, theoretical and numerical studies of gravity waves over mesoscale orography and the underlying ideas behind the parameterization of orographic gravity waves are reviewed. Then a two-dimensional numerical anelastic nonhydrostatic gravity wave model developed is described and results simulated by the model are presented. Through extensive comparisons with the numerically simulated results, it was found that the treatment of low-level wave-breaking and the choice of the parameters representing orography in existing parameterization schemes should be improved: We find that not only the standard deviation of orography, which is the only information regarding orography in existing schemes, but also higher moments of orography, such as the asymmetry and convexity of orography, should be considered. In an attempt to correct these problems, a revised scheme that uses the additional orographic statistics devised was proposed. First, the scheme for isolated orography cases was tested and encouraging results were found. Then complexities caused by the irregularity of orography were investigated and some important considerations on implementing the scheme are presented. Dissert. Abstr.

MODELING OF THE PARTITIONING OF REACTIVE ODD NITROGEN IN THE LOWER STRATOSPHERE USING AIRCRAFT MEASUREMENTS OF NOy, NO, AND OTHER TRACE SPECIES Final Report, 1 May 1991 - 30 Sep. 1992
Stephan Randolph Kawa 1992 4 p
(Grant NAGw-2586)
(NASA-CR-194305; NAS 1.26:194305) Avail: CASI HC A01/MF A01

The objective of this research was to gain a more thorough understanding of the atmospheric processes which control the partitioning of species within the reactive nitrogen (NO(y)) reservoir in the lower stratosphere. This understanding is crucial to predicting ozone loss in the stratosphere. NO(y) is defined as NO + NO2 + HNO3 + N2O5 + ClONO2 + HO2NO2 + NO3 + particulate nitrate. The research focuses on deriving the partitioning among these species using the combined set of measurements from the NASA ER-2 aircraft during recent missions designed to study stratospheric ozone depletion. STORMTIME TRANSPORT OF RING CURRENT AND RADIATION BELT IONS
Margaret W. Chen, Michael Schulz, L. R. Lyons, and David J. Gorney 15 Apr. 1993 19 p See also A93-30815
(Grant NAGw-2126)
(NASA-CR-194416; NAS 1.26:194416; ATR-92(7190)-2) Avail: CASI HC A03/MF A01

This is an investigation of stormtime particle transport that leads to formation of the ring current. Our method is to trace the guiding-center motion of representative ions (having selected first adiabatic invariants mu) in response to model substorm-associated impulses in the convection electric field. We compare our simulation results qualitatively with existing analytically tractable idealizations of particle transport (direct convective access and radial diffusion) in order to assess the limits of validity of these approximations. For mu approximately less than 10 MeV/G (E approximately less than 10 keV at L equivalent to 3) the ion drift period on the final (ring-current) drift shell of interest (L equivalent to 3) exceeds the duration of the main phase of our model storm, and we find that the transport of ions to this drift shell is appropriately idealized as direct convective access, typically from open drift paths. Ion transport to a final closed drift path from an open (plasma-sheet) drift trajectory is possible for those portions of that drift path that lie outside the mean stormtime separatrix between closed and open drift trajectories, For mu approximately 10-25 MeV/G (110 keV approximately less than E approximately less than 280 keV at L equivalent to 3) the drift period at L equivalent to 3 is comparable to the postulated 3-hr duration of the storm, and the mode of transport is transitional between direct convective access and transport that resembles radial diffusion. (This particle population is transitional between the ring current and radiation belt). For mu approximately greater than 25 MeV/G (radiation-belt ions having E approximately greater than 280 keV at L equivalent to 3) the ion drift period is considerably shorter than the main phase of a typical storm, and ions gain access to the ring-current region essentially via radial diffusion. By computing the mean and mean-square cumulative changes in 1/L among (in this case) 12 representative ions equally spaced in drift time around the steady-state drift shell of interest (L equivalent to 3), we have estimated (from both our forward and our time-reversed simulations) the time-integrated radial-diffusion coefficients D(sup sim)(sub LL) for particles having selected values of mu approximately greater than 15 MeV/G. The results agree surprisingly well with the predictions (D(sup ql)(sub LL)) of quasilinear radial diffusion theory, despite the rather brief duration (approximately 3 hrs) of our model storm and despite the extreme variability (with frequency) of the spectral-density function that characterizes the applied electric field during our model storm. As expected, the values of D(sup sim)(sub LL) deduced (respectively) from our forward and time-reversed simulations agree even better with each other and with D(sup sim)(sub LL) when the impulse amplitudes which characterize the individual substorms of our model storm are systematically reduced. This report covers the time period 1 January 1993 to 30 June 1993. During this reporting period we had our third Upper Atmosphere Research Satellite (UARS) correlative balloon flight and submitted the results from this flight to the Central Data Handling Facility (CDHF). We made a number of improvements in our data processing software in preparation for a new analysis of our old balloon data sets. Finally, we continue to analyze the data obtained during the second Airborne Arctic Stratospheric Expedition (AASE 2). Derived from text

ENERGETIC NEUTRAL ATOMS: IMAGING THE MAGNETOSPHERIC RING CURRENT Final Technical Report, 1 Jun. 1985 - 31 Oct. 1989
Edmond C. Roelof 1990 5 p
(Grants NAGw-773; NSF ATM-85-07034)
(NASA-CR-194339; NAS 1.26:194339) Avail: CASI HC A01/MF A01

Magnetospheric imaging is a new discipline whose goal is to make pictures of the energetic particle populations trapped in the magnetic field of Earth (or any other planet). This project demonstrated the technical feasibility and scientific validity of magnetospheric imaging using energetic neutral atoms (ENA) with the publication and quantitative analysis of the first ENA images ever obtained from space. ENA's are produced when singly-charged energetic (approximately 100 keV) trapped ions make an atomic collision with the neutral hydrogen atoms which boil of the top of the Earth's atmosphere. These hydrogen atoms suffuse the entire trapping volume of the magnetosphere. The energetic ion steals the electron from the atmospheric hydrogen, so the energetic ion is transformed into an energetic neutral atom with a velocity of several thousands of kilometers/second. Moreover, the new-born ENA preserves the velocity that the trapped ion had at the time of the collision. Consequently, any population of energetic ions emits ENA's. Derived from text

AEROMAGNETIC WORK IN THE LINCOLN SEA: 1991 SURVEY
J. Bradley Nelson Jul. 1991 16 p
(DSIS-93-00308; DREP-LN-91-06; CTN-93-60750) Avail: CASI HC A03

Aeromagnetic survey work in 1991 included completion of the Lincoln Sea Survey, begun in 1989, and the beginning of the Axel Heiberg Survey scheduled for completion in 1993. Total field, horizontal gradient, and some vertical gradient measurements were obtained. The 1991 total field measurements in the Lincoln Sea have been merged into the 1989 and 1990 data set. A levelled, gridded, total field map and depth to magnetic source analysis for the entire Lincoln Sea Survey area and a levelled, gridded, total field map of the 1991 portion of the Axel Heiberg Survey are presented. Analysis of the 1991 survey data indicates that the short wavelength, low amplitude anomalies just offshore from northern Greenland may be continuations of the faults or volcanics visible onshore. In addition, the magnetic anomalies at the mouth of the Robeson Channel are not consistent with the proposed Wegener Fault running northward into the center of the Lincoln Sea, but the anomaly pattern may be evidence for a motion of 40 km of Greenland relative to Ellesmere Island. Finally, the high amplitude, short wavelength anomalies just offshore from Axel Heiberg Island are continuations of onshore dike structures. Author (CISTI)

In general circulation models (GCM's), some properties of a grid element are necessarily considered homogeneous. That is, for each grid volume there is associated a particular combination of boundary layer depth, vertical profiles of wind and temperature, surface fluxes of sensible and latent heat, etc. In reality, all of these quantities may exhibit significant spatial variations in the grid area, and the larger the area the greater the likely variations. In balancing the benefits of higher resolution against increased computational time and expense, it is useful to consider what the consequences of such subgrid-scale variability may be. Moreover, in interpreting the results of a simulation, one must be able to define an appropriate average value over a grid. There are two aspects of this latter problem: (1) in observations, how does one take a set of discrete or volume-averaged measurements and relate these to properties of the entire domain; and (2) in computations, how can subgrid-scale features be accounted for in the model parameterizations? To address these and related issues, two field campaigns were carried out near Boardman, Oregon, in June 1991 and 1992. These campaigns were designed to measure the surface fluxes of latent and sensible heat over adjacent areas with strongly contrasting surface types and to measure the response of the boundary layer to those fluxes. This paper discusses some initial findings from those campaigns. DOE

A ROCKET-BORNE LIDAR FOR STUDIES OF THE MIDDLE ATMOSPHERE
Torkild Eriksen 19 Oct. 1992 105 p
(FFI/RAPPORT-92/7034; ETN-93-93977) Avail: CASI HC A06/MF A02

The design of an engineering model for a rocketborne instrument for density measurements in the middle atmosphere is described. Such measurements are essential for the knowledge of the energy budget and dynamics in the atmosphere. Rocketborne measurements are a line of research which may improve the accuracy of the density resolution. Resolution calculations are executed for three available transmitters. Different receiver systems and detectors are discussed. Digital and analog signal processing techniques are considered. Analog signal processing with precision components is preferred due to a high signal rate. A complete description of the electronics is included. ESA

STUDIES ON EQUATORIAL SHOCK FORMATION DURING PLASMASPHERIC REFILLING Annual Report, from 1 Aug. 1992
Nagendra Singh 1993 54 p
(Grant NAGw-2128)
(NASA-CR-194392; NAS 1.26:194392) Avail: CASI HC A04/MF A01

During the grant period starting August 1, 1992, our major effort has been on examining the presence of equatorially trapped hot plasma on plasmaspheric refilling. We performed one-dimensional PIC simulations of cold plasmas expanding into a hot plasma, consisting of hot anisotropic ions and warm isotropic electrons, trapped in a region of minimum magnetic field. Simulations showed that the electric potential barrier built up by the anisotropy of the hot ion population facilitates in the formation of electrostatic shocks when the cold ion beams begin to come into contact with the hot plasma. The shock formation occurs even when the cold ion beams are highly supersonic with respect to the ion-acoustic speed. This finding is interesting because equatorial shock formation during the early stage of plasmaspheric refilling has been debated over about two decades. In the past ion-ion instability has been invoked as the main mechanism for the coupling between the cold ion beams approaching the equator from the conjugate ionspheres. This coupling occurs when the beams are sufficiently slow; the beam velocity being less than three times the ion-acoustic speed. In the presence of hot plasma, the beams slow down by the potential barrier. The slowing down and the reflection process lead to the formation of the electrostatic shock even for highly supersonic ion beams. The mixing of hot and cold plasma was also studied. WIND EROSION IN SEMIARID LANDSCAPES: PREDICTIVE MODELS AND REMOTE SENSING METHODS FOR THE INFLUENCE OF VEGETATION Semiannual Status Report, 1 Jan. 1992 - 30 Jun. 1993
H. Brad Musick 30 Jun. 1993 10 p
(Grant NAG5-1833)
(NASA-CR-194029; NAS 1.26:194029) Avail: CASI HC A02/MF A01

The objectives of this research are: to develop and test predictive relations for the quantitative influence of vegetation canopy structure on wind erosion of semiarid rangeland soils, and to develop remote sensing methods for measuring the canopy structural parameters that determine sheltering against wind erosion. The influence of canopy structure on wind erosion will be investigated by means of wind-tunnel and field experiments using structural variables identified by the wind-tunnel and field experiments using model roughness elements to simulate plant canopies. The canopy structural variables identified by the wind-tunnel and field experiments as important in determining vegetative sheltering against wind erosion will then be measured at a number of naturally vegetated field sites and

compared with estimates of these variables derived from analysis of remotely sensed data. Author (revised)

SIMULTANEOUS SOLUTION FOR CORE MAGNETIC FIELD AND FLUID FLOW BENEATH AN ELECTRICALLY CONDUCTING MANTLE

Coerte V. Voorhies and Masahiro Nishihama (Hughes STX, Inc., Lanham, MD.) Sep. 1993 15 p Sponsored by NASA. Washington

(NASA-TM-4536; Rept-93E02367; NAS 1.15:4536) Avail: CASI HC A03/MF A01

The effects of laterally homogeneous mantle electrical conductivity were included in steady, frozen-flux core surface flow estimation along with refinements in method and weighting. The refined method allows simultaneous solution for both the initial radial geomagnetic field component at the core-mantle boundary (CMB) and the sub-adjacent fluid motion; it also features Gauss' method for solving the non-linear inverse problem associated with steady motional induction. The tradeoff between spatial complexity of the derived flows and misfit to the weighted Definitive Geomagnetic Reference Field models (DGRF's) is studied for various mantle conductivity profiles. For simple flow and a fixed initial geomagnetic condition, a fairly high deep-mantle conductivity performs better than either insulating or weakly conducting profiles; however, a thin, very high conductivity layer at the base of the mantle performs almost as well. Simultaneous solution for both initial geomagnetic field and flow reduces the misfit per degree of freedom even more than does changing the mantle conductivity profile. Moreover, when both core field and flow are estimated, the performance of the solutions and the derived flows become insensitive to the conductivity profile. Author

THE ROLE OF IONOSPHERIC PLASMA IN THE MAGNETOSPHERE Final Report, Aug. 1990 - 1993

Gordon R. Wilson Sep. 1993 9 p

(Grant NAG8-822)

(NASA-CR-194404; NAS 1.26:194404) Avail: CASI HC A02/MF A01

During the course of this project we have made a great deal of progress developing and using a new plasma modeling technique which we now refer to as the Generalized Semikinetic (GSK) model. It has been used to study the development of plasma flows in the plasmasphere, the polar cap and auroral zones, and the transition region. Below we describe some of the major accomplishments of this grant. Derived from text

CHEMISTRY AND TRANSPORT IN A MULTI-DIMENSIONAL MODEL Annual Performance Report

Yuk L. Yung 1993 5 p

(Grant NAGw-413)

(NASA-CR-194425; NAS 1.26:194425) Avail: CASI HC A01/MF A01

The focus of our research program is the achievement of a quantitative understanding of the spatial distribution and temporal variation of chemical species in the terrestrial middle atmosphere, with emphasis on ozone. Although not directed at assessments of anthropogenic impacts, our activities contribute to a refinement of model descriptions of chemical and dynamical processes that are needed for assessment tasks. A unique feature of our research effort is a close interaction with the chemical kinetics group at JPL and the field measurement groups at JPL. The principal tools used in our investigations are I-D and 2-D photochemical models. The advective component of the meridional transport in these models is approximated by the diabatic circulation, which is derived diagnostically from the net radiative heating rates. We are developing accurate radiative transfer algorithms to find the net heating rates and the diabatic circulation for use in the 2-D model. Derived from text

IONOSPHERIC CALIBRATION FOR SINGLE FREQUENCY ALTIMETER MEASUREMENTS

William S. Schreiner and George H. Born 31 Aug. 1993 24 p

(Grant NAG1-1491)

(NASA-CR-194282; NAS 1.26:194282) Avail: CASI HC A03/MF A01

This report investigates the potential of using Global Positioning System (GPS) data and a model of the ionosphere to supply a measure of the sub-satellite Total Electron Current (TEC) of the required accuracy (10 TECU rms) for the purpose of calibrating single frequency radar altimeter measurements. Since climatological (monthly mean) models are known to be in error by as much as 50 percent, this work focused on the Parameterized Real-Time Ionospheric Specification Model (PRISM) which has the capability to improve model accuracy by ingesting (adjusting to) in situ ionospheric measurements. A set of globally distributed TEC measurements were generated using GPS data and were used as input to improve the accuracy of the PRISM model. The adjusted PRISM TEC values were compared to TOPEX dual frequency TEC measurements (which are considered truth) for a number of TOPEX sub-satellite tracks. The adjusted PRISM values generally compared to the TOPEX measurements within the 10 TECU accuracy requirements when the sub-satellite track passed within 300 to 400 km of the GPS TEC data or when the track passed through a night time ionosphere. However, when the sub-satellite points were greater than 300 to 400 km away from the GPS TEC data or when a local noon ionosphere was sampled, the adjusted PRISM values generally differed by greater than 10 TECU rms with data excursions from the TOPEX TEC measurements of as much as 40 TECU (an 8 cm path delay error at K band). Therefore, it can be concluded from this analysis that an unrealistically large number of GPS stations would be needed to predict sub-satellite TEC at the 10 TECU level in the day time ionosphere using a model such as PRISM. However, a technique currently being studied at the Jet Propulsion Laboratory (JPL) may provide a means of supplying adequate TEC data to meet the 10 TECU ionospheric correction accuracy when using a realistic number of ionospheric stations. This method involves using global GPS TEC data to estimate a global grid of vertical ionospheric TEC as a function of time (i.e. every one half hour) in a sun-fixed longitude frame. Working in a sun-fixed longitude frame, one is not limited by the spatial decorrelation distance of the ionosphere, but instead is limited more by the temporal correlations of the ionosphere in the sun-fixed frame which are a smaller effect. It is the opinion of the authors that using the global sun-fixed TEC grid data, in particular, ingesting it into PRISM, offers the best possibility of meeting the 10 TECU ionospheric correction accuracy requirement, and should be the subject of further study. FLUXES OF HEAT AND WATER VAPOUR IN A CONVECTIVE MIXED LAYER DURING EFEDA

Berenice I. Michels May 1992 81 p

(DLR-FB-92-21; ETN-93-93738) Avail: CASI HC A05/MF A01

A case study of the transport of sensible and latent heat in a convective boundary layer over complex terrain is presented. The method to analyze turbulence data from Falcon flights during the EFEDA (ECHIVAL Field Experiment for Desertification Threatened Areas) pilot study is described. For two flights of 23 Jun. 1991, a case study is made concerning the vertical flux profiles of heat and water vapor. Both flights include two different legs. The total fluxes are shown, together with a thermodynamic decomposition into different types of motions. The structural development of the atmospheric boundary layer is discussed. The results show different surface characteristics (evaporative fraction) for the two legs, resulting in an atmospheric boundary layer, which is horizontally not uniform but shows significantly different vertical flux profiles throughout the mixed layer. OPTICAL PROPAGATION THROUGH ATMOSPHERIC TURBULENCE. MODEL ANALYSIS OF ANISOPLANATISM AND APPLICATION TO ADAPTIVE OPTICS Ph.D. Thesis - Paris-Sud Univ. [PROPAGATION OPTIQUE A TRAVERS LA TURBULENCE ATMOSPHERIQUE. ETUDE MODALE DE L'ANISOPLANETISME ET APPLICATION A L'OPTIQUE ADAPTATIVE]

Francois Chassat Nov. 1992 204 p In FRENCH

(ONERA-P-1992-4; ETN-93-93967) Avail: CASI HC A10/MF A03

The correction capability of adaptive optics techniques is discussed. The correction capability of these techniques is limited by: no amplitude correction, difference between the sensing, the correcting wavelengths, and anisoplanatism effect. A theoretical analysis of this phenomenon is performed, considering the modal expansion of the wavefronts on the

Zernike polynomials. The spatial correlation of the modal expansion coefficients is derived. The results can be used: to characterize the performance of an adaptive optics system against anisoplanatism; to optimize this performance by tuning up the number of corrected modes; to limit the loss of correction quality due to anisoplanatism by feedback into the correction process. The possibility of working back from the wavefront measurements on a binary star to the profile of the refractive index fluctuations constant is explained. The experiments carried out to investigate the anisoplanatism effects and to validate the theory are presented. ESA

SURVEY OF SUBSURFACE GEOPHYSICAL EXPLORATION TECHNOLOGIES ADAPTABLE TO AN AIRBORNE PLATFORM

K. A. Taylor Dec. 1992 75 p

(Contract DE-AC08-88NV-10617)

(DE93-015080; EGG-10617-1216) Avail: CASI HC A04/MF A01

This report has been prepared by the US Department of Energy (DOE) as part of a Research Development Demonstration Testing and Evaluation (RDDT&E) project by EG&G Energy Measurement's (EG&G/EM) Remote Sensing Laboratory. It examines geophysical detection techniques which may be used in Environmental Restoration/Waste Management (ER/WM) surveys to locate buried waste, waste containers, potential waste migratory paths, and aquifer depths. Because of the Remote Sensing Laboratory's unique survey capabilities, only those technologies which have been adapted or are capable of being adapted to an airborne platform were studied. This survey describes several of the available subsurface survey technologies and discusses the basic capabilities of each: the target detectability, required geologic conditions, and associated survey methods. Because the airborne capabilities of these survey techniques have not been fully developed, the chapters deal mostly with the ground-based capabilities of each of the technologies, with reference made to the airborne capabilities where applicable. The information about each survey technique came from various contractors whose companies employ these specific technologies. EG&G/EM cannot guarantee or verify the accuracy of the contractor information; however, the data given is an indication of the technologies that are available. DOE

TERRESTRIAL MAGNETOSPHERIC IMAGING: NUMERICAL MODELING OF LOW ENERGY NEUTRAL ATOMS

K. R. Moore, H. O. Funsten, D. J. McComas, E. E. Scime, and M. F. Thomsen 1993 13 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, 11-16 Jul. 1993

(Contract W-7405-eng-36)

(DE93-014561; LA-UR-93-1798; CONF-930722-3) Avail: CASI HC A03/MF A01

Imaging of the terrestrial magnetosphere can be performed by detection of low energy neutral atoms (LENA's) that are produced by charge exchange between magnetospheric plasma ions and cold neutral atoms of the Earth's geocorona. As a result of recent instrumentation advances it is now feasible to make energy-resolved measurements of LENA's from less than 1 keV to greater than 30 keV. To model expected LENA fluxes at a spacecraft, we initially used a simplistic, spherically symmetric magnetospheric plasma model. We now present improved calculations of both hydrogen and oxygen line-of-sight LENA fluxes expected on orbit for various plasma regimes as predicted by the Rice University Magnetospheric Specification Model. We also estimate expected image count rates based on realistic instrument geometric factors, energy passbands, and image accumulation intervals. The results indicate that presently proposed LENA instruments are capable of imaging of storm time ring current and potentially even quiet time ring current fluxes and that phenomena such as ion injections from the tail and subsequent drifts toward the dayside magnetopause may also be deduced. (Contract DE-FG02-88ER-13978)

(DE93-015093; DOE/ER-13978/4) Avail: CASI HC A01/MF A01

The older assemblages stand in contrast with the ca. 1000 Ma old Hunting Formation, Arctic Canada, which contains what may be the oldest evidence for modern algae - red algal fossils that compare closely with members of the extant family Bangiophyceae (Butterfield et al., 1990). Taken together the Nonesuch, Shaler, Hunting, and other assemblages support the hypothesis of a major episode of eukaryotic diversification ca. 1000 Ma ago. Prior to this time, eukaryotic primary producers must have been physiologically primitive (and now extinct) algae whose abundance in ecosystems is poorly constrained by analogies with the present oceans. Cyanobacteria were major primary producers in a wide range of marine environments. After 1000 Ma, diversifying red green and chromophyte algae contributed significantly to primary production in all save microbial mat communities in restricted environments. It bears mention that such mat communities remained significant potential sources of buried organic matter until the end of the Proterozoic, necessitating exploration strategies that differ from those commonly employed for younger rocks (Knoll, in press). As in Phanerozoic basins, petroleum exploration in Proterozoic rocks requires tools for stratigraphic correlation. In Neoproterozoic (less than 1000 Ma) rocks, biostratigraphy is possible, and it is aided significantly by C and Sr isotopic chemostratigraphy. New data from the Shaler Group contribute to the construction of C and Sr isotopic curves for Neoproterozoic time, making possible much improved chronostratigraphy for this time interval. DOE

(DE93-010667; ANL/ER/CP-73469; CONF-920134-7) Avail: CASI HC A01/MF A01

In a multilaboratory field study held near Boardman, Oregon, in June 1991, various properties of the surface and lower atmospheric boundary layer over heavily irrigated cropland and adjacent desert steppe were investigated in the initial campaign of the Atmospheric Radiation Measurement (ARM) program. The locale was selected because its disparate characteristics over various spatial scales stress the ability of general circulation models (GCM's) to describe lower boundary conditions, particularly across the discontinuity between desert (in which turbulent flux of heat must be primarily as sensible heat) and large irrigated tracts (in which turbulent flux of latent heat should be the larger term). This campaign of ARM seeks to increase knowledge in three critical areas: (1) determination of the relationships between surface heat fluxes measured over multiple scales and the controlling surface parameters within each scale, (2) integration of local and nearly local heat flux estimates to produce estimates appropriate for GCM grid cells of 100-200 km horizontal dimension, and (3) characterization of the growth and development of the atmospheric boundary layer near transitions between surfaces with strongly contrasting moisture availabilities. ATMOSPHERIC TURBULENCE AND DIFFUSION RESEARCH
R. P. Hosker, Jr. 31 Mar. 1993 66 p
(DE93-011842; ATDL-93011842) Avail: CASI HC A04/MF A01

The Atmospheric Turbulence and Diffusion Division (well known in the atmospheric dispersion community as the Atmospheric Turbulence and Diffusion Laboratory (ATDL)) is one of several field facilities of NOAA's Air Resources Laboratory, headquartered in Silver Spring, Maryland. The laboratory conducts research on matters of atmospheric diffusion and turbulent exchange, concerning air quality. ATDD focuses attention on the physics of the lower atmosphere, with special emphasis on the processes contributing to atmospheric transport, dispersion, deposition, and air-surface exchange, and on the development of predictive capabilities using the results of this research. Research is directed toward issues of national and global importance related to the missions of DOE, to DOE's Oak Ridge Field Office, and to NOAA. The program is divided into four major projects: plume transport and diffusion in the planetary boundary layer, complex topography, canopy micrometeorology, and air-surface exchange. DOE

SNOW COVER MODELS IN OPERATIONAL WATERSHED FORECASTING
B. Vehvilaeinen 1992 112 p
(DE93-778332; VYH-PUB-11) Avail: CASI HC A06/MF A02

This study deals with water quality and acidification of 12 small lakes in the proposed national park area of Repovesi in 1990 - 1991. Water samples were taken also from two big lakes, Lake Repovesi and Lake Tihvetjaervi. Diatoms and metals were analyzed from a sediment profile of a small clearwater lake. The national acidification research project (HAPRO) included none of the lakes in the Repovesi area. The small lakes were mainly clearwater lakes with the exception of one humic pond. They were oligotrophic. The buffer capacity against acidification was very low. Two of the lakes were permanently acidic. Sulphate was the dominating anion except in the humic pond. Acid snowmelt waters increased markedly the nitrate nitrogen contents under the ice cover. Acidification models showed that alkalinity values have decreased much in the small lakes. Comparison between the old (from the 1960's) and new water quality results showed also the development of acidification e.g., in water color and in chemical oxygen demand. However, acidification was not evident in the paleolimnological investigations of one of the lakes. The diatoms reflected above all the clarity of water. The dominate species were Cyclotella kuetzingiana var. radiosa and C. kuetzingiana. The forestry measures in the nearby catchment area of the lake were poorly reflected in the diatom flora. Acidification in the Repovesi area is not as advanced as in the headwaters south of Salpausselkae or e.g., in the Nuuksio area in northern Espoo. The water quality of Lake Repovesi is classified as excellent. Lake Tihvetjaervi is mesotrophic. Risks to water protection consist of air pollution and of possible forestry measures. DOE

THE APPLICATION OF VAS SATELLITE IMAGERY TO THUNDERSTORM FORECASTING AT CAPE CANAVERAL Final Report, 1 Aug. 1988 - 29 Apr. 1993
Henry E. Fuelberg 12 Aug. 1993 4 p
(Grant NAG10-0047)
(NASA-CR-193563; NAS 1.26:193563; FSU-1338-592-26) Avail: CASI HC A01/MF A01

The Final Report on the application of VAS satellite imagery to thunderstorm forecasting at Cape Canaveral is presented. The objective of this research was to investigate whether satellite-derived imagery and derived products could be used advantageously in forecasting thunderstorms in the Cape Canaveral area. Specifically, data from the VISSR Atmospheric Sounder that is housed on the current series of GOES geostationary meteorological satellites was used. These satellite data were used extensively in the middle latitudes, but their utility over central Florida where the climate is more tropical had not been examined. Derived from text

A PARAMETERIZATION OF CLOUD DROPLET NUCLEATION
S. J. Ghan, C. Chuang, and J. E. Penner (Lawrence Livermore National Lab., CA.) Jan. 1993 7 p Presented at the 4th American Meteorological Society Symposium on Global Change Studies, Anaheim, CA, 14-19 Jan. 1993
(Contract DE-AC06-76RL-01830)
(DE93-007998; PNL-SA-20914; CONF-930142-4) Avail: CASI HC A02/MF A01

Droplet nucleation is a fundamental cloud process. The number of aerosols activated to form cloud droplets influences not only the number of aerosols scavenged by clouds but also the size of the cloud droplets. Cloud droplet size influences the cloud albedo and the conversion of cloud water to precipitation. Global aerosol models are presently being developed with the intention of coupling with global atmospheric circulation models to evaluate the influence of aerosols and aerosol-cloud interactions on climate. If these and other coupled models are to address issues of aerosol-cloud interactions, the droplet nucleation process must be adequately represented. Here we introduce a droplet nucleation parametrization that offers certain advantages over the popular Twomey parameterization. DOE

DMSP F11 SSM/T-2 CALIBRATION AND VALIDATION Final Report, Jan. - Nov. 1992
V. Falcone, M. K. Griffin, R. G. Isaacs, J. D. Pickle, and J. F. Morrissey 29 Oct. 1992 447 p
(AF Proj. 6670)
(AD-A265817; PL-TR-92-2293; ERP-1111) Avail: CASI HC A19/MF A04

Calibration and validation of the Defense Meteorological Satellite Program (DMSP) Special Sensor Microwave Water Vapor Sounder (SSM/T-2) is investigated. The objective of the effort is to obtain simultaneous independent measurements of microwave radiance, water vapor mass, specific humidity, and relative humidity to quantitatively measure the performance of the instrument (calibration) and to validate the ability of the SSM/T-2 to measure the water vapor parameters, i.e. the environmental data records (EDRs) of Air Force Global Weather Central (AFGWC). Analysis of satellite and aircraft data for calibration using both underflights and radiative transfer calculation show that the SSM/T-2 is performing within or exceeds the original contract specifications (1K). The SSM/T-2 retrieved vertical moisture profiles (EDRs) are performing within the contract specification of +/- 30 RH when compared with collocated radiosonde data except over certain ocean atmospheres. ON THE VERTICAL STRUCTURE OF SEASONAL, INTERANNUAL AND INTRASEASONAL FLOWS M.S. Thesis
Steven R. Gilbert Dec. 1992 200 p
(AD-A265346; AFIT/CI/CIA-92-30D) Avail: CASI HC A09/MF A03

The vertical structure of the height and wind fields associated with the seasonal, interannual, and intraseasonal cycles is documented by making use of global ECMWF operational analyses for seven pressure levels (1000-100 mb) and spanning a 10 year period (1980-89). The role of tropical convection is examined for each of these time scales. The seasonal cycle is described through the structure of the geopotential height field standing waves, the vertical structure of the first seven wavenumbers of the rotational and divergent winds, and latitude/time cross-sections for the vertical structure of the planetary waves. The change in the vertical structure from the internal mode combinations found in the tropics to a dominant external mode of the extratropics occurs rapidly and within 10 deg of the convective source regions. Extensive use is made of a primitive equation (PE) model, as a diagnostic tool, to explore the extent to which tropical heating might influence the extratropical vertical structure. The PE response indicates the possibility that 25-40% of the Northern Hemisphere and 30-55% of the Southern Hemisphere kinematic vertical structure could be the result of tropical heating. Two significant El Nino Southern Oscillation (ENSO) events occur during this 10 year period and their vertical structures are examined. The cold phase is found to be dominated by higher internal modes than the warm phase. This may be linked to different air-sea interactive processes during cold and warm ENSO phases. DTIC

LINKAGE OF ANTHROPOGENIC AEROSOL TO CLOUDS AND CLIMATE
J. G. Hudson 14 Dec. 1992 24 p
(Contract DE-FG08-90ER-61012)
(DE93-016434; DOE/ER-61012/T3) Avail: CASI HC A03/MF A01

During the first year of this project, equipment was built to obtain direct droplet measurement data from a mobile platform in fog (or mountain impacted stratum) and to characterize CCN according to particle volatility (thermal processing). Since the start date, 15 July 1990, was during the California stratus season, and it was necessary to complete the construction of equipment and allow time before a field project, it was not possible to begin field work until the summer of 1991. This report discusses surface measurements made in 1991 and 1992 as well as the SEAHUNT (Shiptrail Evolution Above High Updraft Naval Targets) Project and the ASTEX (Atlantic Stratocumulus Transition Experiment) Project. The major focus of this CHAMMP science team project is the development and in-model testing of new numerical methods and dynamical algorithms which are particularly well suited to massively parallel computers. The project includes efforts relevant to both global ocean circulation models and atmospheric General Circulation Models (GCM's) During the first year of the project we have been focusing on two basic areas. The first of these is the implementation and testing of a global non-linear dynamics code using the Local Spectral (LS) formalism. During the first year of the CHAMMP project we have been focusing on developing an efficient parallel implementation of a spherical LS code on a massively parallel computer. Our initial implementation platform has been the Thinking Machines CM5 system. We have completed an initial implementation of the LS system on the CM5 using a semi-spectral partitioning where the convolution sums in the LS kernel are computed using direct convolutions in the meridional direction and FFT based fast convolutions are performed using the Winnograd method in the zonal direction. A second element of the first year effort has been the evaluation of alternate dynamical systems for use in global ocean circulation models. In this area, we have concentrated our efforts on parabolic non-hydrostatic systems using artificial compressibility. DOE

CYCLOGENESIS AND CYCLONE OVER SOUTH AMERICA Ph.D. Thesis [CICLOGENESES E CICLONES SOBRE A AMERICA DO SUL]
Manoel Alonso Gan Apr. 1992 212 p In PORTUGESE
(INPE-5400-TDI/479) Avail: CASI HC A10/MF A03

The propose of this study is to establish the most frequent place and season for cyclogenesis and to describe the mechanisms that cause cyclogenesis in South America region. A 10 year (1979-1988) climatological study of surface cyclogenesis is done. The results show that the higher frequency of cyclogenesis occurs during the winter and the lower frequency occurs during the summer time. The interannual variation was also examined. The winter of 1983, 1986, and 1987 'El Nino' years presented higher frequency of cyclogenesis while the winter of 1981 (positive Southern Oscillation Index) presented a minimum. Winters of maximum (minimum) frequency of cyclogenesis are associated with above (bellow) normal precipitation over Southern Brazil. The results of a linear quasi-geostrophic multilevel model, with latent heat release, show that the seasonal and interannual variations of the frequency of cyclogenesis are associated with baroclinics mechanisms. The two case studies (summer and winter) show that baroclinic and orographic mechanisms are responsible for cyclogenesis. The winter case shows that baroclinic mechanisms are responsible for cyclogenesis. The effect of topographic wave is noted in the cyclone's initial path. The summer case shows that cyclogenesis is caused by effects of orography and the cyclone intensification by baroclinic effects. A correlation analysis of both unfiltered and high-pass filtered geopotential height data showed the occurrence of a wavelike pattern moving to east and tilting to west with the height. The orographic effects appear when the wave gets close to the Andes Cordillera. The wavelike pattern that appears in the high-pass filtered data suggests a spatial structure and a displacement similar to the most unstable normal modes of quasi-geostrophic model with mountain range placed in north-south direction. LIGHTNING SIMULATION AND DETERMINATION OF EXPECTED STRIKING POINTS M.S. Thesis
Inna Nissenbaum Dec. 1991 73 p In HEBREW
(ITN-93-85202) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

A dynamic model was developed for the propagation of a lightning

leader stroke, and a general algorithm was developed, which does not depend on boundary conditions. The numerical method was selected to match the calculation speed and memory capacity of an AT personal computer. In contrast to other models, which check field strength values at discrete points, the model described here facilitates calculations throughout the region of interest, and includes the nonlinear effects of local discharges. C language and BGI graphics are used and the software provides both color-graphic and numerical display of the results, comprising electric field strength and potential values. The model was used to calculate expected strike points. The results were not verified experimentally, but comparisons with published theoretical and field results indicated satisfactory agreement. PRELIMINARY METEOROLOGICAL RESULTS FOR 1992 WEST COAST SCOTLAND EXPERIMENT
H. F. Robey Jan. 1993 17 p
(Contract W-7405-eng-48)
(DE93-014677; UCRL-ID-112984) Avail: CASI HC A03/MF A01

This memo documents preliminary meteorological results from the 1992 West Coast Scotland Experiment, a joint US/UK radar ocean imaging experiment. Measurements of wind speed and direction are reported for both phases of the experiment covering the periods from 7-13 June and from 19-25 June. The measurements were obtained using a Campbell Scientific CR10 Datalogger and R. M. Young model 03001-5 anemometer and wind vane. The anemometer has a resolution of 0.1 m/s and the wind vane 1 deg, but the motion of the ship platform reduces the precision of the direction measurements to +/- 10 deg. Data were downloaded to an IBM PC-AT for final storage and analysis. The anemometer was mounted at a height of 10 meters above the mean water surface on top of a mast located at the bow of the Royal Marine Auxiliary Service (RMAS) tug, Cairn. The Cairn was moored at the center of the experiment site at 57 deg 7.13755 min N, 5 deg 44.88521 min W in the Sound of Sleat, nominally 200 meters from the ship track. Wind velocity and direction were recorded at a sample rate of 0.2 Hz, and the averaged value was output every 10 minutes from approximately 2 hours before the start of the first run to 2 hours after the end of the last run. Data are plotted in the following pages in 2 formats for a quick visual summary of the daily wind conditions. The top plot gives wind velocity (m/s) and direction (deg true) vs time given in minutes relative to the start of the first run which is designated as T. The lower plot gives a polar plot of the same data with velocity on the radial axis and direction on the azimuthal axis. The final two plots give a summary of the wind speed vs direction for phase 1 (7-13 June) and phase 2 (19-25 June). DOE

SPATIAL VARIABILITY OF THROUGHFALL CHEMISTRY IN A TROPICAL RAINFOREST (CENTRAL AMAZONIA, BRAZIL)
Maria Cristina Forti and Colin Neal (Institute of Hydrology, Wallingford, England.) 1992 20 p Repr. from The Science of the Total Environment (Amsterdam, Netherlands, Elsevier Science Publishers B.V.), v. 120, 1992 p 245-259
(INPE-5431-PRE/1765) Avail: CASI HC A03/MF A01

A statistical analysis is made on throughfall data for a location in a 'terra firme' rain forest in central Amazonia. The results show a large variability in water and chemical fluxes. For all the ions there is a variance in the mean value due to the positions of sample collectors. Despite the large variability, throughfall volume is correlated with rainfall. This is not the case for any of the chemicals studied. The use of a transect design with collectors at variable positions is shown to be sound. It is concluded that to obtain flux estimates to within 10 percent of the mean at 90 percent confidence level, about 300 collections are required for the wet period and 200 collections are required for the dry period. It is proposed that in future studies, a minimum of 20 roving gages over as wide an area as practical be employed to achieve reliable estimates. Sampling programs should run for a period of at least one year. Author (revised)

REMOTE IDENTIFICATION OF RAIN AND HAIL WITH A POLARIZATION DIVERSITY RADAR Ph.D. Thesis
Kais J. L. Al-Jumily 1989 203 p
(ISBN-0-315-55623-4; CTN-93-60733) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

Measurements made with a 2.88 GHz circular polarization diversity radar are compared with ground based observations of precipitation to improve the use of polarization methods for distinguishing hail from rain. Case studies involve light and heavy rain and rain/hail mixtures selected to represent the spectrum of precipitation rate, location, type, and duration. Propagation effects due to precipitation between the radar and target and the way in which they can be recognized and removed from radar measurements are incorporated into the evaluation. These improve data interpretation and thereby better determine the polarization characteristics of precipitation particles. Relations developed between the reflectivity factor and polarization parameters show that certain combinations of reflectivity and polarization measurements can be used to discriminate between rain and hail regions in storms and that neither reflectivity nor polarization measurements can be considered separately. A new technique, based on a combination of reflectivity and differential reflectivity derived from circular polarization measurements after propagation effects are removed, is developed for remote identification of rain and hail with radar. The method is tested on ground based observations. Results show that predicted hail regions correlate well with the surface hail pattern. Author (CISTI)

STORM PREDICTION THROUGH BAROMETRIC FIELD ANALYSIS [CONTRIBUTION A LA PREVISION DES ORAGES PAR L'ANALYSE DU CHAMP DE TENDANCE BAROMETRIQUE]
Martine Vertez 1992 62 p In FRENCH
(Publ-Ser-A-129; ETN-93-94379) Avail: CASI HC A04/MF A01

A study, whose aim was to bring more certitude to the prediction of when storms would break out and the extent of their violence, is reported. The theory of storms, what they are, and the different types that occur are considered. Theories of convection are discussed and meteorological observations of wind, pressure, rain, temperature, and humidity are considered. The use of satellite images in storm prediction is discussed. A case study which analyzes the information available at the time of the outbreak of the storm in the Brussels (Belgium) region on 2 Jul. 1991 is presented. The following are considered in this analysis: atmospheric situation, synoptic observations, radar maps, barometric maps, variations in temperature and humiduty, wind, and rain. ESA

DESCRIPTION OF THE EURAD CHEMISTRY-TRANSPORT MODEL. VERSION 2 (CTM2)
Heinz Hass 1991 106 p
(Rept-83; ETN-93-94384) Avail: CASI HC A06/MF A02

A limited area mesoscale Chemistry Transport Model (CTM), a comprehensive Eulerian air quality model, is described. This model simulates various chemical and physical processes that are thought to be important for understanding of the tropospheric trace gas distributions. Modeling the deposition of these gases is another important aspect in the CTM system. A description of the entire CTM2 modeling system in a more technical sense is given. The physical and chemical concepts of each submodule are described. Preprocessing information is given about how to run the model. Technical information like flow charts, array structures etc. are given in the appendix. ESA

ESTIMATIONS OF TEMPERATURE AND HUMIDITY OF THE CANOPY IN AMAZON FOREST USING MICROWAVE DATA FROM SMMR SENSOR OF NIMBUS-7 SATELLITE M.S. Thesis [ESTIMATIVAS DA TEMPERATURA E UMIDADE DO DOSSEL NA FLORESTA AMAZONICA, UTILIZANDO DADOS DE MICROONDAS DO SENSOR SMMR DO SATELITE NIMBUS-7]
Jorge Luis Silva Brito Sep. 1992 108 p In PORTUGESE Original contains color illustrations
(INPE-5444-TDI/490) Avail: CASI HC A06/MF A02

The forest canopy humidity and temperature of the region of Manaus (3 deg S, 60 deg W) have been estimated for the 1985 wet (April-May) and dry (July-August) seasons at 12:00 and 00:00 local standard time,

from spaceborne microwave radiometer, along with microwave emission models. The satellite data consist of SMMR (Scanning Multichannel Microwave Radiometer) Nimbus-7 corrected brightness temperatures for the 6.6, 10.7, 18.0 and 37.0 GHz frequencies. To model the signal emitted by the forest canopy, two different numerical models were used: a discrete model, which calculates the scattering and absorbing coefficients of each bioelement of the canopy (stems, branches and leaves), and a continuous model, which uses a statistical description of the canopy dielectric properties canopy. Micrometeorological data obtained from the GTE/ABLE-2A (GLOBAL Tropospheric Experiment/Amazon Boundary Layer Experiment 2A), and ARME (Anglo-Brazilian Amazon Region Micrometeorological Experiment) at the Duck Reserve (2 deg 57 min S, 59 deg 57 min W) have been used. A sensitivity study of the models has also been conducted to evaluate the influence of the moisture, temperature gradient and vegetal biomass on the brightness temperatures simulated by the models. The sensitivity test has indicated that it is necessary to use both the 37.0 GHz and low frequencies to carry out the inversion of the structure parameters, moisture and temperature. The moisture values obtained through the inversion of the continuous model have been consistent with the ones obtained by other authors in field experiments in the Amazon region. A moisture index has been defined (normalized difference of the optimized moisture at 37.0 and 6.6 GHz frequencies), and has shown to be a good index of the vegetation stomatal resistance. Author

STUDY ON TRMM DATA UTILIZATION FOR METEOROLOGY [TRMM DETA NO KISHOU BUNYA ENO RIYOU NI KANSURU CHOUSA KENTOU]
National Space Development Agency 31 Mar. 1993 72 p In JAPANESE
(NASDA-CNT-930007; JTN-93-80461) Avail: CASI HC A04/MF A01

TRMM (Tropical Rainfall Measuring Mission), which will be launched around 1996 jointly by Japan and the U.S., intends to observe three dimensional distributions of precipitation in the tropical and subtropical regions between 37 deg N and 37 deg S from space by using precipitation radar and other instruments. Data obtained by TRMM is expected to play an important role in research and operational fields related to precipitation. Especially, it is anticipated that TRMM data will be very useful for understanding the many varieties of meteorological phenomena, in which precipitation is a key factor. This report summarizes the expected research plans using TRMM data inside and outside Japan, based on the results of several scientific meetings. It became clear that about 100 scientists want to use TRMM data for their research works and that their research subjects are distributed very widely, such as precipitation climatology, precipitation systems in the tropics and subtropics, validation of the atmospheric general circulation models, improvement of numerical weather forecast model, flood forecast, and so on. Also, it can be noticed that about 50 members of the science team are actively performing the TRMM research programs in the U.S. and that other nations are also quite interested in TRMM.

CLIMATIC CHANGE DUE TO LAND SURFACE ALTERATIONS
Sergio H. Franchito and V. Brahmananda Rao 1992 38 p
(INPE-5495-PRE/1786) Avail: CASI HC A03/MF A01

A primitive equations global zonally averaged climate model is developed. The model includes biofeedback mechanisms. For the Northern Hemisphere the parameterization of biofeedback mechanisms is similar to that used by Gutman et al. For the Southern Hemisphere new parameterizations are derived. The model simulates reasonably well the mean annual zonally averaged climate and geobotanic zones. Deforestation, desertification, and irrigation experiments are performed. In the case of deforestation and desertification there is a reduction in the surface net radiation, evaporation, and precipitation and an increase in the surface temperature. In the case of irrigation experiment opposite changes occurred. In all the cases considered the changes in evapotranspiration overcome the effect of surface albedo modification. In all the experiments changes are smaller in the Southern Hemisphere. Author (revised)

WEATHER FORECASTING SUPPORT FOR AASE-2 Final Report, 1 Oct. 1991 - 30 Mar. 1992
Gregory S. Forbes 22 Apr. 1992 5 p
(Grant NAGw-2792)
(NASA-CR-194342; NAS 1.26:194342) Avail: CASI HC A01/MF A01

The AFEAS Contract and NASA Grant were awarded to Penn State in order to obtain real-time weather forecasting support for the NASA AASE-II Project, which was conducted between October 1991 and March 1992. Because of the special weather sensitivities of the NASA ER-2 aircraft, AASE-II planners felt that public weather forecasts issued by the National Weather Service would not be adequate for mission planning purposes. A likely consequence of resorting to that medium would have been that scientists would have had to be at work by 4 AM day after day in the hope that the aircraft could fly, only to be frustrated by a great number of 'scrubbed' missions. Thus, the Pennsylvania State University was contracted to provide real-time weather support to the AASE-II mission.

MANUAL ON THE GLOBAL DATA-PROCESSING SYSTEM. VOLUME 1: (ANNEX 4 TO THE WMO REGULATIONS) GLOBAL ASPECTS (1992 EDITION)
1992 104 p
(WMO-485-Vol-1; ISBN-9-26-312485-X; ETN-93-94373) Copyright Avail: CASI MF A02; print copy available at WMO, Geneva, Switzerland

The manual on the Global Data Processing System (GDPS), which was designed to facilitate cooperation in data processing between members, to specify obligations of members in the implementation of the World Weather Watch (WWW) GDPS, and to ensure adequate uniformity and standardization in the practices and procedures employed in achieving the aforementioned, is presented. The manual consists of volumes 1 and 2, which deal with global and regional aspects respectively. Volume 1 of the manual covers: organization and functions of the GDPS; data processing for real time uses; and data processing for nonreal time uses which contain regulatory material for the global aspects of the WWW GDPS. The regulatory material stems from recommendations of the Commission for Basic Systems (CBS) as well as from decisions taken by Congress and the Executive Council. This volume, on global aspects, forms part of the Technical Regulations and is referred to as Annex 4 to the Technical Regulations. ESA

COHERENT DOPPLER LIDAR SIGNAL COVARIANCE INCLUDING WIND SHEAR AND WIND TURBULENCE
R. G. Frehlich 1 Sep. 1993 13 p Sponsored in part by NSF
(Grant NAG8-253)
(NASA-CR-194492; NAS 1.26:194492) Avail: CASI HC A03/MF A01

The performance of coherent Doppler lidar is determined by the statistics of the coherent Doppler signal. The derivation and calculation of the covariance of the Doppler lidar signal is presented for random atmospheric wind fields with wind shear. The random component is described by a Kolmogorov turbulence spectrum. The signal parameters are clarified for a general coherent Doppler lidar system. There are two distinct physical regimes: one where the transmitted pulse determines the signal statistics and the other where the wind field dominates the signal statistics. The Doppler shift of the signal is identified in terms of the wind field and system parameters. Author (revised)

AMIP: DIAGNOSTIC SUBPROJECT ON THE VARIABILITY IN THE TROPICS: SYNOPTIC TO INTRASEASONAL TIME SCALES
K. R. Sperber, J. M. Slingo, A. Matthews (European Centre for Medium-Range Weather Forecasts, Reading, England.), and T. N. Palmer Dec. 1992 6 p Presented at the 17th Annual Climate Diagnostics Conference, Norman, OK, 19-23 Oct. 1992
(Contract W-7405-eng-48)
(DE93-009287; UCRL-JC-112366; CONF-9210334-1) Avail: CASI HC A02/MF A01

The aim of this subproject is to evaluate the ability of GCM's to simulate the transient component of tropical convection and to increase

our understanding of the possible processes that govern the development, propagation, and dissipation of synoptic disturbances and the intraseasonal oscillation. A pilot study of the tropical variability in a high resolution version of the ECMWF model has already shown that a GCM may have considerable skill in simulating the observed distribution and periodicities of tropical disturbances. Verification of the model results will involve satellite data and NWP analyses. In particular, a similar study of the observed intraseasonal oscillation using EC analyses, being carried out as part of the Joint Diagnostics Project at Reading University, will form an important part of the verification of this subproject. In this paper we present a preliminary evaluation of the intraseasonal oscillation as simulated by the ECMWF model. This simulation, with a horizontal resolution of T42 (approximately 2.8 deg), was performed at Lawrence Livermore National Laboratory on behalf of the European Center for Medium-Range Weather Forecasts. (DE93-010712; LA-UR-93-857; CONF-9303122-1) Avail: CASI HC A03/MF A01

Recent interest in understanding climate and climate change at regional-scales has led to the application of mesoscale models for regional climatology studies. These models can provide an understanding of climate processes in a physically consistent way at much higher resolution than presently offered by GCM's. In recent work, we have tried to address questions in the RAMS mesoscale model to establish confidence in our modeling procedure. A more rigorous comparison of our modeling results with various data sets is reported. In the present paper, we use two simple numerical experiments to examine the impact of grid configuration on the predicted precipitation field from the RAMS model. We intend to demonstrate that the choice of the lateral boundaries and grid configurations can significantly impact the predicted fields of interest. DOE

The manual on the Global Data Processing System (GDPS), which was designed to facilitate cooperation in data processing between members, to specify obligations of members in the implementation of the World Weather Watch (WWW) GDPS, and to ensure adequate uniformity and standardization in the practices and procedures employed in achieving the aforementioned, is presented. The manual consists of volumes 1 and 2, which deal with global and regional aspects respectively. Volume 2 contains the regional and national aspects of the WWW GDPS based on the practices and procedures adopted by the regional associations and by members concerned as well as relevant decisions of Congress, the Executive Council and the Commission for Basic Systems. This volume is divided into sections corresponding to the six regions of the World Meteorological Organization, namely: Africa, Asia, South America, North and Central America, south west Pacific, Europe. Each of these regions is divided into three parts: real time data processing (regional and national aspects); nonreal time processing (regional and national aspects); and monitoring of the GDPS (regional and national aspects). Data processing activities and meteorological services in the Antarctic are also covered. ESA

CIRCULATION AND RAINFALL CLIMATOLOGY OF A 10-YEAR (1979 - 1988) INTEGRATION WITH THE GODDARD LABORATORY FOR ATMOSPHERES GENERAL CIRCULATION MODEL
J.-H. Kim (Applied Research Corp., Landover, MD.) and Y. C. Sud Sep. 1993 228 p
(RTOP 913-00-00)
(NASA-TM-104591; Rept-93B00105; NAS 1.15:104591) Avail: CASI HC A11/MF A03

A 10-year (1979-1988) integration of Goddard Laboratory for Atmospheres (GLA) general circulation model (GCM) under Atmospheric Model Intercomparison Project (AMIP) is analyzed and compared with observation. The first momentum fields of circulation variables and also hydrological variables including precipitation, evaporation, and soil moisture are presented. Our goals are (1) to produce a benchmark documentation of the GLA GCM for future model improvements; (2) to examine systematic errors between the simulated and the observed circulation, precipitation, and hydrologic cycle; (3) to examine the interannual variability of the simulated atmosphere and compare it with observation; and (4) to examine the ability of the model to capture the major climate anomalies in response to events such as El Nino and La Nina. The 10-year mean seasonal and annual simulated circulation is quite reasonable compared to the analyzed circulation, except the polar regions and area of high orography. Precipitation over tropics are quite well simulated, and the signal of El Nino/La Nina episodes can be easily identified. The time series of evaporation and soil moisture in the 12 biomes of the biosphere also show reasonable patterns compared to the estimated evaporation and soil moisture.

CCL WORKING GROUP ON CLIMATE DATA AND ITS RAPPORTEURS Final Report
Nov. 1992 86 p Presented at the Eleventh Session of the Commission for Climatology, Havana, Cuba, 15-26 Feb. 1993
(WCDMP-21; WMO-TD-523) Avail: CASI HC A05/MF A01; print copy available at WMO, Geneva, Switzerland

This collection of the Working Group's individual reports documents the progress being made in climate data management. The presented information includes pilot projects for improving data quality and product distribution for climate system monitoring; systematic monitoring of the global climate system; reference climatological stations (RCS); global and regional baseline data sets for climate change studies; climate data management in developing countries; CLICOM (climate computing); INFOCLIMA - a valuable approach to climate data sources; and climate related issues connected with the conversion of conventional meteorological stations to automatic ones.

A radiative transfer model is developed for the simulation of millimeter wavelength radiances emerging from cloudy and precipitating atmospheres over oceans and different land surfaces. The model fully accounts for multiple scattering as well as for polarization effects caused by hydrometeors and the surface. A sensitivity analysis for the estimation of the influence of different surface types on the emitted radiation is carried out. For land surfaces only the variation of the vertical component of the emitted radiation with the surface conditions is small enough to be used for the retrieval of atmospheric parameters. A global set of 340 atmospheric radiosondes is used in order to simulate the dual polarized radiometer signals as measured in all spectra channels of the Special Sensor Microwave Imager (SSM/I). An error analysis of the effect of spatial inhomogeneity on the retrievals shows no systematic impact of fractional cloud and rain coverage within a pixel, except for water vapor, because of droplet absorption becoming effective also at frequencies of water vapor absorption. The retrieval algorithms are applied to SSM/I passive microwave soundings of Aug. 1987 for global maps of water vapor, precipitation and total water content. A preliminary comparison with surface climatologies, satellite measured rainrate from infrared soundings and an experiment with a general circulation model shows that the values are reliable within the range of sampling errors.

SEA SURFACE TEMPERATURE FORCING AND PHASE LOCKING OF NORDESTE PRECIPITATION
K. R. Sperber and S. Hameed (State Univ. of New York, Stony Brook.) Jul. 1992 4 p Presented at the 7th Brazilian Meteorological Congress: Climate Change and the Environment, San Paulo, Brazil, 28 Sep. - 2 Oct. 1992
(Contracts W-7405-eng-48; DE-FG02-85ER-60314)
(DE93-011873; UCRL-JC-109819; CONF-9209331-1) Avail: CASI HC A01/MF A01

Interannual variations of precipitation in several regions around the globe are known to be influenced by sea surface temperatures. We describe a procedure that elicits the same frequencies of variations in the sea surface temperatures as in precipitation. The modes of variations in the two fields are phase locked, allowing us to identify regions in the oceans that vary in unison with changes in precipitation on different time scales. The method is illustrated by application to northeast Brazil, the Nordeste, where flood and drought occur frequently.

A 1-dimensional SVAT-model (Soil Vegetation Atmosphere Transfer Model) is presented. It is composed of three coupled submodels: a multilayer soil model, a vegetation model, and a multilayer model of the planetary boundary layer. The complete model can also be run without the planetary boundary model if wind, humidity, and temperature are prescribed at the upper boundary of the vegetation model. An additional driving force is the absorbed solar and atmospheric longwave radiation. The output are among other things the turbulent sensible and latent heat fluxes, the leaf temperature, profiles of soil temperature and soil water content and, if coupled with the boundary model, profiles of potential temperature, specific humidity and wind. The vegetation model is based upon the BATS (Biosphere Atmosphere and Transfer Scheme) model, in which many improvements and extensions were implemented. As for the soil, the equations of water and heavy transfer are solved. The model equations of the planetary boundary layer consist of Ekman equations and the balance equations for enthalpy and water vapor. To verify the model, the output is compared with data sampled in the field. The case of dense vegetation and relatively humid soil for three sunny days is treated. Altogether very good agreement is found.

The influence of clouds on the radiation field and on climate is

investigated over the North Sea by analyzing NOAA AVHRR (Advanced Very High Resolution Radiometer) data. The main interest is on high clouds due to their ambivalent behavior in the radiation field. The first step was an accurate detailed cloud classification based on the infrared likelihood method. A further step is the determination of optical properties of high clouds. The derived information was applied to calculate the cloud-climate efficiency at the top of atmosphere and at the surface. The analysis of the data set shows that the monthly mean cloud forcing of Oct. 1990 is larger than in Oct. 1989 due to a larger amount of high clouds and less low level clouds in the North Sea. A first approach of a comparison of the increasing cloud forcing (heating of the Earth atmosphere system) and an analysis of the relative topography 300/850 hPa shows that the increase of the cloud forcing is well correlated with an increase of the temperature in this layer. The deviation from the long term mean of the pressure or temperature shows the same behavior. ESA

(Grant BMFT-07-KFT-05/6)
(Rept-93; ETN-93-94191) Avail: CASI HC A08/MF A02

A detailed description of the third generation atmospheric general circulation model ECHAM is presented. The climatology of ECHAM3, as simulated at low and high resolution (T21 and T42, respectively), is compared with ECMWF (European Center for Medium range Weather Forecasts) analyses (1981 to 1990) and also with the climatology of two earlier low resolution versions ECHAM1 and ECHAM2. At low resolution, the impact of the improved model physics is evident primarily in the simulated time-mean state which is more successfully reproduced by the more recent model versions, particularly by ECHAM3. The impact of increased horizontal resolution can be identified not only by a generally improved time-mean circulation, particularly in the southern hemisphere, but most significantly by the increased level of high frequency variability. In the low frequency range, however, the impact of increased horizontal resolution is modest, and all models fail to reproduce the observed level of low frequency intraseasonal variability. ESA

OCEAN ACOUSTIC PROCESSING: A MODEL-BASED APPROACH
J. V. Candy and E. J. Sullivan (Naval Underwater Systems Center, Newport, RI.) Jul. 1992 8 p Presented at the Oceans 1992, Newport, RI, 26-29 Oct. 1992 Revised
(Contract W-7405-eng-48)
(DE93-011902; UCRL-JC-107852-Rev-1; CONF-921066-3-Rev-1) Avail: CASI HC A02/MF A01

A model-based approach is proposed to solve the ocean acoustic signal processing problem that is based on a state-space representation of the normal-mode propagation model. This model is generalized to the stochastic case where an approximate Gauss-Markov model evolves which allows the inclusion of stochastic phenomena such as noise and modeling errors in a consistent manner. Based on this framework, investigations are made of model-based solutions to the signal enhancement and related parameter estimation problems. DOE

CIRCULATION MODEL EXPERIMENTS OF THE GULF STREAM USING SATELLITE-DERIVED FIELDS Final Report
Daniel N. Fox, Michael R. Carnes, and Jimmy L. Mitchell Apr. 1993 48 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A266067; NRL/FR/7323-92-9412; NOARL-55) Avail: CASI HC A03

The ability to perform skillful forecasts of the space and time evolution of mesoscale ocean phenomena can significantly improve acoustic surveillance capabilities, search and rescue operators, the performance of weapon systems, and other aspects of naval operations. The Ocean Dynamics and Prediction Branch, Ocean Monitoring and Prediction Section of the Naval Research Laboratory (NRL), Stennis Space Center, MS, is developing an ocean nowcast/forecast capability to permit dynamical interpolation of the limited number of in situ and satellite observations available using a hierarchy of coupled hydrodynamic and thermodynamic models. A series of numerical experiments to predict the evolution of the Gulf Stream were performed. These experiments led to the first system to show significant skill in this area. The forecast system uses the NRL Northwest Atlantic regional primitive equation model and assimilation schemes. The schemes employ both a feature model and statistical correlations derived from the regional climatology of in situ data and long time-base numerical simulations. DTIC

PRELIMINARY RESULTS ON THE HYDROLOGICAL MEASUREMENTS IN THE AEGEAN SEA OFF CRETE: CRUISE, GEORGIA, 1989
Giuseppina Mattietti and Volfango Rupolo 1989 39 p
(Preprint-736; ETN-93-94372) Avail: CASI HC A03/MF A01

Data collected during the short oceanographical cruise 'Georgia 89' during which measurements of pure density and salinity were carried out are presented. These data were collected by means of a Kiel Multisonde ME 1500 bathysonde. The data were processed with an Olivetti m280 computer. Samples of deep marine water were also collected with a Rosette multisampler in order to measure the oxygen content at various depths. Together with the data, the following figures are presented: general map of the working zone with hydrological stations; bathymetric map of the working zone; diagrams of the hydrological stations; maps of potential temperature, salinity and density at various depths; isopycnals of the hydrological sections; vertical profiles of the oxygen values; maps of oxygen values at various depth; satellite thermal information of the sea surface. Dave R. Lyzenga Mar. 1993 75 p
(Contract N00014-90-C-0071)
(AD-A266339; ERIM-225300-8-F) Avail: CASI HC A04/MF A01

A model for the short surface wave spectrum is presented, which includes the effects of wind forcing, surfactant damping, wave-current interactions, and wave breaking. A new analytical solution of the wave action equation was developed in order to account for wave-current interactions. The wave breaking model is based on a threshold criterion involving the vertical acceleration. The breaking fraction is then calculated as a function of the slope variance, and the backscatter is calculated from the Kirchhoff model by assuming a Gaussian correlation function within the breaking regions. Model predictions are compared with synthetic aperture radar observation made during the ONR/NRL High Resolution field experiment. DTIC

MAXIMUM ENTROPY SPECTRAL ANALYSIS OF THE GEOLOGICAL TIME SERIES OF THE OXYGEN ISOTOPE RECORD FROM DEEP-SEA CORES
Rajaram Purushotam Kane and Nalin Babulal Trivedi 1993 30 p Submitted for publication
(INPE-5465-PRE/1773) Avail: CASI HC A03/MF A01

A Maximum Entropy Spectral Analysis of the geological time series of the oxygen isotope 18 for the last 782,000 years showed 98,000 years as the most prominent periodicity, followed by 40,000 years of less than half the amplitude and still smaller peaks at 24,000, 67,000, 84,000, 107,000 and 786,000 years. Among the astronomical parameters, only eccentricity showed a similar periodicity viz. 96,000 years. Obliquity had a prominent periodicity at 41,000 years which was reflected in the oxygen isotope series also. Corresponding to the bimodal precession peaks (23,000 and 19,000 years), the oxygen isotope series showed a peak at 24,000 years and smaller peaks at 22,000 and 19,000 years. Our results compare well with those obtained by Thomson (1990) with a more sophisticated method. Author

VOLUME 14: THE FIRST SeaWiFS INTERCALIBRATION ROUND-ROBIN EXPERIMENT, SIRREX-1, JULY 1992
James L. Mueller (San Diego State Univ., CA.), Stanford B. Hooker, ed., and Elaine R. Firestone, ed. (General Sciences Corp., Laurel, MD.) Sep. 1993 62 p Its SeaWiFS Technical Report Series
(NASA-TM-104566; Rept-93B00117-Vol-14; NAS 1.15:104566) Avail: CASI HC A04/MF A01

The results of the first Sea-viewing Wide Field-of-view Sensor (SeaWiFS) Intercalibration Round-Robin Experiment (SIRREX-1), which was held at the Center for Hydro-Optics and Remote Sensing (CHORS) at San Diego State University (SDSU) on 27-31 July 1992 are presetend. Oceanographic radiometers to be used in the SeaWiFS Calibration and Validation Program will be calibrated by individuals from the National Aeronautics and Space Administration's (NASA's) Goddard Space Flight Center (GSFC), CHORS,

and seven other laboratories. The purpose of the SIRREX experiments is to assure the radiometric standards used in all of these laboratories are referenced to the same scales of spectral irradiance and radiance, which will be maintained by GSFC and periodically recalibrated by the National Institute of Standards and Technology (NIST). The spectral irradiance scale of GSFC's FEL lamp number F269 (recalibrated by NIST in October 1992) was transferred to lamps belonging to the 9 participating laboratories; I set of lamp transfer measurements (involving 4 of the lamps) was precise to within less than 1 percent and meets SeaWiFS goals, but a second set (involving another 14 lamps) did not. The spectral radiance scale of the GSFC 40-inch integrating sphere source was transferred to integrating sphere radiance sources belonging to four of the other laboratories. Reflectance plaques, used for irradiance-to-radiance transfer by five of the laboratories, were compared, but spectral bidirectional reflectance distribution functions (BRDF's) were not determined quantitatively. Also reported are results of similar comparisons (in October 1992) between the GSFC scales of spectral irradiance and radiance and those used by the Hughes/Santa Barbara Research Center (SBRC) to calibrate and characterize the SeaWiFS instrument. This first set of intercalibration round-robin experiments was a valuable learning experience for all participants, and led to several important procedural changes, which will be implemented in the second SIRREX, to be held at CHORS in June 1993. ON THE SPACE-TIME OCEAN CURRENT VARIABILITY AND ITS EFFECTS ON THE LENGTH-OF-DAY Ph.D. Thesis
Nikolaos Theodoros Christou Jul. 1990 355 p
(ISBN-0-315-59510-8; CTN-93-60856) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

The time dependent perturbations of length of day (LOD), on time scales of about two years or less, associated with the space-time fluctuations of the global ocean circulation, are quantified. Estimates of the space-time variations of ocean currents were derived from both in-situ oceanographic data and two years of satellite altimetry observations from the GEOSAT Exact Repeat Mission. A new technique for extracting ocean current variability from satellite altimetry was developed, based on the gradient operator. The technique offers advantages over previous techniques on the recovery of oceanic variability in that it is conceptually simple and computationally efficient. Through analysis of ocean current variability, it is established that the oceanic excitation of LOD is at least at the level of 0.1 ms. Variations in the oceanic excitation of Delta-LOD have been identified and quantified at periods of 1 year and 0.5 years. At the annual period, the results indicate that the oceanic excitation appears large enough to account for the existing discrepancy between the observed (non-tidal) LOD and the atmospheric contribution. No significant oceanic excitation of Delta-LOD is found at the semiannual period. The results also indicate that there exist statistically significant higher frequency variations at about 121-, 107-, and 89-day periods. Author (CISTI)

COASTAL SCOUR PROBLEMS AND METHODS FOR PREDICTION OF MAXIMUM SCOUR Final Report
Jimmy E. Fowler May 1993 73 p
(AD-A266658; CERC-TR-93-8) Avail: CASI HC A04/MF A01

The most common coastal scour-related problems are to scour at rubble-mound structures and vertical seawalls and at the base of piles and horizontal pipelines. Existing scour prediction methods for these problems vary from rules of thumb to empirically derived equations to theoretically derived relationships. Recent studies at the U.S. Army Engineer Waterways Experiment Station's Coastal Engineering Research Center indicate that sufficient design guidance exists for vertical walls, pipelines, and vertical piles; however, additional research is still needed for rubble-mound structures. CATALYSIS AND BIOCATALYSIS PROGRAM Final Report, May 1980 - 31 Dec. 1991
J. D. Ingham 1 May 1993 68 p
(Contract DE-AI01-86CE-90239)
(NASA-CR-194105; JPL-Publ-93-04; NAS 1.26:194105) Avail: CASI HC A04/MF A01

This final report presents a summary of research activities and accomplishments for the Catalysis and Biocatalysis Program, which was renamed the Biological and Chemical Technologies Research (BCTR) Program, currently of the Advanced Industrial Concepts Division (AICD), Office of Industrial Technologies of the Department of Energy (DOE). The Program was formerly under the Division of Energy Conversion and Utilization Technologies (ECUT) until the DOE reorganization in April, 1990. The goals of the BCTR Program are consistent with the initial ECUT goals, but represent an increased effort toward advances in chemical and biological technology transfer. In addition, the transition reflects a need for the BCTR Program to assume a greater R&D role in chemical catalysis as well as a need to position itself for a more encompassing involvement in a broader range of biological and chemical technology research. The mission of the AICD is to create a balanced Program of high risk, long-term, directed interdisciplinary research and development that will improve energy efficiency and enhance fuel flexibility in the industrial sector. Under AICD, the DOE Catalysis and Biocatalysis Program sponsors research and development in furthering industrial biotechnology applications and promotes the integrated participation of universities, industrial companies, and government research laboratories. MONOCLONAL ANTIBODIES DIRECTED AGAINST SURFACE MOLECULES OF MULTICELL SPHEROIDS Semiannual Status Report, 1 Jan. - 30 Jun. 1993
Andrew O. Martinez 1993 10 p
(Grant NAG2-819)
(NASA-CR-193560; NAS 1.26:193560) Avail: CASI HC A02/MF A01

The objective of this project is to generate a library of monoclonal antibodies (MAb's) to surface molecules involved in the cell-cell interactions of mammalian cells grown as multicell spheroids (MCS). MCS are highly organized 3-dimensional multicellular structures which exhibit many characteristics in vivo tissues not found in conventional monolayer or suspension culture. They also provide a functional assay for surface adhesion molecules. In brief, MCS combine the relevance of organized tissues with the accuracy of in vitro methodology. Further, one can manipulate these MCS experimentally to discern important information about their biology. Author (revised)

ROLE OF Ca(++)/CALMODULIN IN THE REGULATION OF MICROTUBULES IN HIGHER PLANTS
R. Cyr 1992 7 p
(Contract DE-FG02-91ER-20050)
(DE93-015885; DOE/ER-20050/T1) Avail: CASI HC A02/MF A01

The cytoskeleton including its microtubule (Mt) component participates in processes that directly affect growth and development in higher plants. Normal cytoskeletal function requires the precise and orderly arrangement of Mts into several cell cycle and developmentally specific arrays. The cortical array somehow directs the deposition of cellulose. Little molecular information is available regarding the formation of these arrays or the cellular signals to which they respond. Experimental data described here suggests that plant cells use calcium, in the form of a Ca(sup ++)/calmodulin complex, to affect the dynamics of Mts within the cortical array. Owing to the importance of Ca(sup ++) as a regulatory ion in higher plants we are probing for a putative Ca(sup ++)/Mt transduction pathway which may serve to integrate Mt activities within the growing and developing plant cell. We are using a lysed cell model in conjunction with immunocytochemical and biochemical methodologies to dissect how Ca(sup ++)/calmodulin interacts with Mts to affect their function. DOE

EVOLUTION OF CATALYTIC RNA IN THE LABORATORY Final Technical Report, 1 Apr. 1989 - 31 Mar. 1992
Gerald F. Joyce 31 Mar. 1992 7 p
(Grant NAGw-1671)
(NASA-CR-194124; NAS 1.26:194124) Avail: CASI HC A02/MF A01

We are interested in the biochemistry of existing RNA enzymes and in the development of RNA enzymes with novel catalytic function. The focal point of our research program has been the design and operation of a laboratory system for the controlled evolution of catalytic RNA. This system serves as working model of RNA-based life and can be used to explore the catalytic potential of RNA. Evolution requires the integration of three chemical processes: amplification, mutation, and selection. Amplification results in additional copies of the genetic material. Mutation operates at the level of genotype to introduce variability, this variability in turn being expressed as a range of phenotypes. Selection operates at the level of phenotype to reduce variability by excluding those individuals that do not conform to the prevailing fitness criteria. These three processes must be linked so that only the selected individuals are amplified, subject to mutational error, to produce a progeny distribution of mutant individuals. We devised techniques for the amplification, mutation, and selection of catalytic RNA, all of which can be performed rapidly in vitro within a single reaction vessel. We integrated these techniques in such a way that they can be performed iteratively and routinely. This allowed us to conduct evolution experiments in response to artificially-imposed selection constraints. Our objective was to develop novel RNA enzymes by altering the selection constraints in a controlled manner. In this way we were able to expand the catalytic repertoire of RNA. Our long-range objective is to develop an RNA enzyme with RNA replicase activity. If such an enzyme had the ability to produce additional copies of itself, then RNA evolution would operate autonomously and the origin of life will have been realized in the laboratory. CLINICAL PHYSIOLOGY OF BED REST
John E. Greenleaf Apr. 1993 27 p
(RTOP 199-18-12-07)
(NASA-TM-104010; A-93058; NAS 1.15:104010) Avail: CASI HC A03/MF A01

Maintenance of optimal health in humans requires the proper balance between exercise, rest, and sleep as well as time in the upright position. About one-third of a lifetime is spent sleeping; and it is no coincidence that sleeping is performed in the horizontal position, the position in which gravitational influence on the body is minimal. Although enforced bed rest is necessary for the treatment of some ailments, in some cases it has probably been used unwisely. In addition to the lower hydrostatic pressure with the normally dependent regions of the cardiovascular system, body fuid compartments during bed rest in the horizontal body position, and virtual elimination of compression on the long bones of the skeletal system during bed rest (hypogravia), there is often reduction in energy metabolism due to the relative confinement (hypodynamia) and alteration of ambulatory circadian variations in metabolism, body temperature, and many hormonal systems. If patients are also moved to unfamiliar surroundings, they probably experience some feelings of anxiety and some sociopsychological problems. Adaptive physiological responses during bed rest are normal for that environment. They are attempts by the body to reduce unnecessary energy

expenditure, to optimize its function, and to enhance its survival potential. Many of the deconditioning responses begin within the first day or two of bed rest; these early responses have prompted physicians to insist upon early resumption of the upright posture and ambulation of bedridden patients. PHYSIOLOGICAL ANATOMICAL RODENT EXPERIMENT (PARE) .04 FEASIBILITY TEST 1
Hubert W. Burden 22 Sep. 1993 73 p
(Contract NCC2-810)
(NASA-CR-194423; NAS 1.26:194423) Avail: CASI HC A04/MF A01

The objective of this feasibility study was to investigate the environmental/treatment stresses in the proposed PARE.04 experiments in a ground based study to determine if these stresses were of sufficient magnitude to compromise the planned shuttle experiments. Eighty pregnant Sprague-Dawley rats were received on day 2 (day I equals day of vaginal plug) of gestation (G2) and on G7 60 were laparotomized to determine the condition of pregnancy and allow assignment to test groups. The five test groups (N equals 10 each group) were as follows: Group 1, nominal flight; Group 2, laparotomy control; Group 3, hysterectomy control; Group 4, vivarium control; Group 5, caesarean delivery. On G17, groups 1, 2, and 5 were subjected to unilateral hysterectomy to obtain fetuses for evaluation. There was no difference in fetal crown-rump length, fetal weight, or placental weight in any of the test groups subjected to unilateral hysterectomy at G17. Animals were allowed to go to term and animals in each group delivered between the morning of G22 and the afternoon of G23. Rats assigned to Group 5 began delivering vaginally prior to the designated time for caesarean section, thus only 2 animals in this group were delivered by caesarean section. After delivery, a blood sample was taken from the dam, and they were euthanized and the thymus and adrenal glands weighed. Pups from experimental dams were tattooed for identification, the anogenital distance of male pups was photographed for later measurement, and all pups placed with foster dams and litter sizes were standardized to 10. On day 7, all pups were euthanized, and pup adrenal glands and thymus weighed. Laparotomy at G7 with or without unilateral hysterectomy at G17, had no effect on pregnancy maintenance or vaginal delivery. There was no difference in maternal adrenal or thymus weights or plasma levels of catecholamines, estradiol, progesterone, or corticosterone. Likewise, there was no difference in the anogenital distance (index of fetal stress) of neonatal male pups, between any of the experimental groups. From days 0-7, weight gain from dams in all experimental groups was similar. Lastly, there was no difference in weights of thymus and adrenal glands in pups euthanized at day 7. Collectively, these data indicate that treatment stresses inherent in the proposed PARE.04 experimental design should not compromise the planned shuttle experiments.

N-ethylmaleimide (NEM) inhibits the ATPase of H. saccharovorum in a nucleotide protectable manner. The bulk of 14C-NEM is incorporated into subunit 1. Inhibition kinetics indicated a single binding site. To determine the sequence around this site, cyanogen bromide peptides of NEM-labeled ATPase enzyme were prepared and separated on Tris-Tricine gels. Autoradiography indicated that the NEM binding site is probably located in a fragment of Mr 10-12 K. This result will be confirmed by N-terminal sequencing of the peptide. Since the cysteinyl residue, to which NEM is bound, may be located at the C-terminal end, purification and proteolytic treatment of the 10 K peptide will be required. One inhibitor of V-type ATPases, fluoresceinisothiocyanate (FITC) inhibited also the ATPase of H. saccharovorum. Preliminary results indicated protection against inhibition by nucleotides. Localization of the binding sited to the major subunits is in progress. An extraction procedure for the membrane sector of the ATPase complex of H. saccharovorum yielded a preparation which was enriched in a peptide of Mr 5 500. Experiments to test the immunological crossreaction with subunit c from the Escherichia coli F-type ATPase and the labeling with 14C-DCCD are currently carried out. Polyclonal antiserum to the smaller of the major subunits of the ATPase from H. saccharovorum (subunit II) reacts in Western blots strongly with the alpha and beta subunits of the F1 ATPase of E. coli, suggesting highly conserved regions on both types of ATPases. To elucidate further the regions of homology, cyanogen bromide peptides of the beta subunits were prepared for sequence analysis.

GORDON RESEARCH CONFERENCE ON CHRONOBIOLOGY, 1991 Final Report, 1 Aug. 1991 - 31 Jul. 1992
J. W. Hastings 31 Jul. 1992 9 p Conference held in Irsee, Germany, 29 Sep. - 4 Oct. 1991
(Grant AF-AFOSR-0280-91)
(AD-A266354; AFOSR-93-0447TR) Avail: CASI HC A02/MF A01

The 1991 Gordon Conference on Chronobiology was held at the Swabian Conference Center in Irsee, Germany, from 29 Sep. - 4 Oct. 1991. The possibility of holding the conference in Europe was known at the previous (1989) meeting, and conferees voted to do so if the opportunity materialized. Probably more than most, the field of chronobiology embraces many subdisciplines, ranging from molecular biology and genetics to physiology and ecology. It is also diverse in terms of biological material, including all Kingdoms and spanning the phylogenetic spectrum. It is relevant to many specific missions, such as medicine and pharmacology, agriculture, and insect control, as well as marine biology and oceanography. The program thus reflects the wish and the willingness of workers in this area to consider a diversity of functions and a diversity of systems, ranging from nitrogen fixation in bacteria, photosynthesis and luminescence in marine dinoflagellates and CAB gene expression in wheat, to conidiation in Neurospora, eclosion in Drosophila, and activity in rodents and man.

The effectiveness of ginseng saponin (GS) as an ergogenic agent was evaluated and the mechanisms through which GS elicits its beneficial effect on exercise performance were elucidated. Short term (2-4 days) pretreatment with GS significantly prolonged the aerobic endurance of mature young and old rats exercising at 70 percent maximum oxygen volume. Results indicated that either a proto-panaxadiol triterpenoid or a proto-panaxatriol triterpenoid purified from GS were essential for eliciting the beneficial ergogenic effects of GS. Compared to saline treated control rats, GS significantly increased the plasma free fatty acid level of the animals at rest and during exercise. During exercise, the plasma glucose level of the control group declined progressively, whereas in the GS-treated animals it maintained a stable level. Both the liver and skeletal muscle glycogen levels of the GS-treated rats were slightly higher than those of the control animals after exhaustive exercise. These results indicate that GS enhances exercise endurance by altering fuel homeostasis during prolonged exercise, presumably by increasing free fatty acid utilization in preference of glucose for cellular energy production. (NASA-CR-194176; NAS 1.26:194176) Avail: CASI HC A02/MF A01

The results of several experiments were disseminated professionally during this semiannual period. These peer-reviewed papers that were accepted for publication represent the growth of our research areas, as follow-up experiments to previously published work in cognition and enrichment have been completed and are being published. The presentations not only reflect the latest interesting results that we have obtained, but also serve as a testament to the intense interest that is being expressed for our test system and findings. METABOLIC RATE MEASUREMENTS COMPARING SUPINE WITH UPRIGHT UPPER-BODY EXERCISES
Suzanne M. Fortney, Michael C. Greenisen, Karin C. Loftin, Donya Beene, Sondra Freeman-Perez, and Linda Hnatt Sep. 1993 22 p
(Contract NAS9-18492)
(NASA-CR-4549; S-736; NAS 1.26:4549) Avail: CASI HC A03/MF A01

The ground-based study that tested the hypothesis that metabolic rates during supine and upright upper-body exercises are similar (mean value of 200 kcal/h) is presented. Six subjects each performed supine or upright exercise at three exercise stations, a hand-cycle ergometer, a rope-pull device, and a torque wrench. After a baseline measurement of the metabolic rate at rest, the metabolic rate was measured twice at each exercise station. The mean metabolic rates (kcal/h) during supine (n = 6) and upright control (n = 4) exercise stations were not significantly different except for the rope-pull station, 153.5 +/- 16.6 (supine) as compared to 247.0 +/- 21.7 (upright), p is less than 0.05. This difference may be due in part to an increased mechanical efficiency of supine exercises (15.0 +/- 0.7 percent) as compared to that of upright exercises (11.0 +/- 1.08 percent), p is less than 0.05. The net energy input was significantly smaller for the supine rope-pull exercise (64 +/- 18) as compared to upright (176 +/- 20). The relationship between best-rest exercises, metabolic rates, and the incidence of decompression sickness (DCS) should be examined to determine the true risk of DCS in spaceflight extravehicular activities.

VARIABILITY OF PREDICTION OF MAXIMAL OXYGEN CONCUMPTION ON THE CYCLE ERGOMETER USING STANDARD EQUATIONS
Michael C. Greenisen, Suzanne M. Fortney, Stuart M. C. Lee (Krug Life Sciences, Inc., Houston, TX.), Alan D. Moore (Krug Life Sciences, Inc., Houston, TX.), and Linda H. Barrows (Krug Life Sciences, Inc., Houston, TX.) Sep. 1993 11 p
(NASA-TP-3412; S-737; NAS 1.60:3412) Avail: CASI HC A03/MF A01

Several investigations within the Exercise Countermeasures Project at the NASA Johnson Space Center focused on the assessment of maximum oxygen consumption (VO2(sub max)) within the Astronaut Corps pre- and postspace flight. Investigations during the Apollo era suggested that there was a significant decrease in postflight VO2(sub max) when compared to preflight values, and current studies have documented that this trend continues in the Space Shuttle era. It is generally accepted and was confirmed in our laboratory that VO2(sub max) can be predicted from submaximal measures taken during graded exercise tests on the cycle ergometer with respect to populations. However, previous work had not examined the effect of day-to-day variations in the physiologic responses that might alter these predictions for individuals. Stability of individual submaximal data over serial tests is important so that predicted changes in VO2(sub max) are reflective of actual VO2(sub max) changes. Therefore, the purpose of this investigation was to determine which of the accepted equations to predict VO2(sub max) would be less affected by normal daily physiologic changes.

CHARACTERIZATION OF SPIRULINA BIOMASS FOR CELSS DIET POTENTIAL
Mahasin G. Tadros Aug. 1993 41 p
(Contract NCC2-501)
(NASA-CR-194123; NAS 1.26:194123) Avail: CASI HC A03/MF A01

Cyanobacteria, Spirulina maxima as a biogenerative photosynthetic and an edible alga for the space craft crew in a CELSS, was evaluated in an effort to increase the growth rate, biomass, yield, and chemical analysis in continuous cultures. The cell characteristics were determined for cultures maintained at steady state with respect to the substrate concentration. The productivity increased in experiments exposed to low light (30 uE m(exp -2)s(exp -1). Oxygen evolved and protein production were higher in cultures exposed to low light intensity. There was a relationship between nitrate concentration and the yield of the culture. Increasing the concentration of nitrate in the growth medium up to 20 mM was enough to produce a culture having the same chemical composition as that of complete medium. High light was inhibiting the yield of the culture. Increasing the concentration of phosphate beyond 1 mM did not improve the yield of the culture. Increasing the concentration of sodium chloride in the growth medium did not affect the growth of the alga up to 0.1 M but beyond that the culture started to be stressed. The response to stress appeared in high production of total carbohydrate on the expense of protein production. The oxygen production was also higher in cultures stressed with sodium chloride.

THE SURFACE-LOCATED YopN PROTEIN IS INVOLVED IN CALCIUM SIGNAL TRANSDUCTION IN YERSINIA PSEUDOTUBERCULOSIS
A. Forsberg, A.-M. Viitanen (Turku Univ., Finland.), M. Skurnik (Turku Univ., Finland.), and H. Wolf-Watz (Umea Univ., Sweden.) 1991 10 p Repr. from Molecular Microbiology, v. 5, no. 4, 1991 p 977-986 Sponsored by Sigrid Juselius Foundation; Emil Aaltonen Foundation; and Farmos Research and Science Foundation
(Grants SMRC-07490-040; BU-4426-30; STuF-90-00577)
(FOA-B-40416-4.4; ETN-93-93761) Avail: CASI HC A02/MF A01

The low calcium response is strongly conserved among the pathogenic Yersinia species and is observed when the pathogen is grown at 37 C in Ca(2+) depleted medium. This response is characterized by a general metabolic downshift and by a specific induction of virulence plasmid encoded Yop (Yersinia outer membrane protein) genes. Regulation of the Yop expression is exerted at a transcriptional level by a temperature regulated activator and by Ca(2+) regulated negative elements. The YopN gene was shown to encode a protein (formerly also designated Yop4b) which is surface located when Yersinia is grown at 37 C. YopN was found to be part of an operon that is induced during the low calcium response. Insertional inactivation of the YopN gene resulted in derepressed transcription of Yop genes. A hybrid plasmid containing the YopN gene under the control of the tac promoter fully restored the wild type phenotype of the YopN mutant. Thus, the surface located YopN somehow senses the calcium concentration and transmits a signal to shut off Yop transcription when the calcium concentration is high.

ANALYSIS OF THE V ANTIGEN lcrGVH-yopBD OPERON OF YERSINIA PSEUDOTUBERCULOSIS: EVIDENCE FOR A REGULATORY ROLE OF LcrH AND LcrV
Thomas Bergman (Umea Univ., Sweden.), Sebastian Haakansson (Umea Univ., Sweden.), Aake Forsberg, Lena Norlander, Anna Macellaro, Assar Baeckman (Umea Univ., Sweden.), Ingrid Boelin, and Hans Wolf-Watz (Umea Univ., Sweden.) 1991 10 p Repr. from Journal of Bacteriology, v. 173, no. 5, Mar. 1991 p 1607-1616
(Grants SMRC-07490-040; BU-4426-30; STuF-90-00577)
(FOA-B-40417-4.4; ETN-93-93762) Copyright Avail: CASI HC A02/MF A01

It is shown that the V antigen containing operon of Yersinia pseudotuberculosis is a polycistronic operon having the gene order lcrGVH-YopBD. Deoxyribonucleic Acid (DNA) sequencing analysis of lcrGVH revealed a high homology to the corresponding genes of Yersinia pestis. LcrG was conserved and LcrH showed only one amino acid different, while LcrV showed only 96.6% identity. The amino acid substitutions of LcrV occurred in the central domain of the protein, while the two ends of the protein were conserved. Northern (ribonucleic Acid (RNA)) blotting experiments showed that the operon is regulated at the transcriptional level by the extracellular stimuli temperature and calcium. One 4.6 Kb transcriptional product of the operon was identified. The mRNA is rapidly processed at its 5' end, resulting in different mRNA species of variable stability. By genetic analysis, the lcrV and lcrH gene products were found to be regulatory proteins having important roles in the Ca(2+) controlled regulation of Yop (Yersinia outer membrane protein) expression. The activity of LcrH is modulated by a gene product of the operon that inhibits the negative action of LcrH on Yop transcription in the absence of Ca(2+).

CELLULAR RESPONSES TO LOW-GRAVITY: PILOT STUDIES ON SUBORBITAL ROCKETS AND ORBITING SPACECRAFT Final Report, 1 Oct. 1991 - 30 Sep. 1993
Marian L. Lewis 30 Sep. 1993 40 p

(Grant NAGw-2739)
(NASA-CR-194402; NAS 1.26:194402) Avail: CASI HC A03/MF A01

The allocated funding supported, in part, experiments conducted on two Consort sounding rockets and five Shuttle flights. The primary parameters investigated were signal transduction in response to various mediators, cellular differentiation and metabolism in microgravity, and effect of microgravity on cytoskeletal morphology. Achievements include: demonstration of effect of spaceflight on the actin cytoskeleton in mouse osteoblasts and frog cells; confirmation that the T cell receptor-mediated signal transduction pathway in T lymphocytes is not affected by low-gravity compared to non-TCR-mediated stimulation (Con-A) which classically does not promote proliferative response; indication that microgravity may allow separation of proliferative signaling and secretory function in lymphocytes; demonstration that T lymphocytes and bone cells utilized less glucose indicating a shift in metabolism and confirming Spacelab results with WI-38 cells which used significantly less glucose, during spaceflight; confirmation that activation of human splenic B cells with a number of different mediators is not affected during spaceflight; demonstration of increased prostaglandin synthesis during reduced bone cell growth suggesting an effect of microgravity on prostaglandin-induced mitogenesis. The funding contributed significantly to the database described above and resulted in submission of six collaborative abstracts in 1993 (five to the ASGSB Annual Meeting and one to the ASCB Annual Meeting). Two abstracts were presented at the 1992 ASGSB Annual Meeting in Tucson. In addition, several peer reviewed papers are being generated and data will be included as background in preparation of future proposals, which hopefully will allow us to continue this type of extremely productive collaborative research.

(DE93-014398; DOE/ER-13734/4) Avail: CASI HC A01/MF A01

Glu-tRNA(sup Glu) is synthesized from glutamate and tRNA(sup Glu) by glutamyl-tRNA synthetase (GluRS). Recent work has demonstrated that Glu-tRNA(sup Glu) has dual functions and is a precursor for protein and 5-aminolevulinate (ALA) synthesis. Current data does not provide compelling evidence for the notion that GluRS is regulated by chlorophyll precursors or in concert with the other enzymes of ALA synthesis. We have redefined the C5-pathway as a two-step route to ALA starting with Glu-tRNA(sup Glu). Only two enzymes, Glu-tRNA reductase (GluTR) and GSA-2,1-amino-mutase (GSA-AM), are specifically involved in ALA synthesis. We have purified these enzymatic activities from Chlamydomonas and demonstrated that the two purified proteins in the presence of their cofactors NADPH and pyridoxal phosphate are sufficient for the in vitro Glu-tRNA (yields) ALA conversion. We have cloned the genes encoding GluTR. The sequences of the GluTR proteins deduced from these genes share highly conserved regions with those of bacterial origin. We have also cloned and analyzed the gene encoding GSA-AM from Arabidopsis. As in Salmonella typhimurium, there are indications of the existence of an additional pathway for ALA formation in E. coli. To shed light on the recognition of the single tRNA(sup Glu) by the chloroplast enzymes GluTR, GluRS, we characterized a chlorophyll-deficient mutant of Euglena having tRNA(sup Glu) with a point mutation in the T(Psi)C-loop. The altered tRNA supports protein but not ALA synthesis. DOE

CHAOS AND MICROBIAL SYSTEMS
M. Kot Oct. 1992 5 p
(Contract DE-FG06-90ER-61034)
(DE93-016814; DOE/ER-61034/2) Avail: CASI HC A01/MF A01

The field of nonlinear dynamics has generated a variety of new techniques for identifying order in seemingly chaotic systems. These techniques have led to new insights for several ecological and epidemiological systems, most notably childhood disease epidemics. To better test the efficacy and relevance of these new techniques to population biology research with two components namely a mathematical analysis of some simple microbial models with chaotic dynamics; and experimental (chemostat) population studies to evaluate the accuracy of these models. I have completed a thorough analysis of the forced double-Monod model and of the phase-locking route to chaos that it exhibits. I have also analyzed a simpler pulsed system with mass action kinetics and a period-doubling route to chaos. This research also motivated detailed analyses of discrete-time predator-prey and dispersal models, and a fast new method for computing fractal dimension. My colleagues and I have assembled a complete laboratory system to determine the appropriateness of the forced double-Monod model. We have tested assays for concentration and density and have performed a variety of diagnostic tests on this system. We have measured growth parameters for bacteria and for protozoa in chemostat. This report discusses our work during the last 3 years using x-ray diffraction and shear measurements to study lipid monolayers (membranes). The report is divided into: (1) structure--phase diagram of saturated fatty acid Langmuir monolayers, effect of head group interactions, and studies of transferred monolayers (LB films); and (2) mechanical properties--fiber optic capillary wave probe and centrosymmetric trough, mechanical behavior of heneicosanoic acid monolayer phases. A CHARACTERIZATION OF CARBOXYLESTERASES IN RAT AND GUINEA PIG: THEIR HETEROGENEITY AND ROLE IN DETOXICATION OF ORGANOPHOSPHORUS COMPOUNDS Ph.D. Thesis - Oslo Univ.
Rolf Gaustad Sep. 1993 51 p
(NDRE-Publ-93-1001) Avail: CASI HC A04/MF A01

The present study deals with the molecular properties of carboxylesterases (CarbEs) and the ability of the various isoenzymes to detoxify organophosphorus compounds. CarbE isoenzymes have been separated from lungs, livers, plasma and small intestines of rats and guinea pigs mainly by chromatofocusing. One of the isoenzymes in rat lung, pI 5.8, has been purified to near homogeneity. This isoenzyme has a molecular mass of approx 180 kDa with subunits of 60 kDa, and by Edman degradation the first 19 amino acid residues were determined. Monoclonal antibodies (MAbs) were prepared against the purified isoenzyme and used in enzyme-linked immunosorbent assays (ELISA) to distinguish between the CarbE isoenzymes in the different tissues. The molecular and immunological results showed a strong relationship between lung CarbE, pI 5.8, and the rat liver CarbE, pI 6.0. The MAbs were strongly bound to the high pI forms of the CarbE isoenzymes in plasma and small intestine from rats and guinea pigs, but not to the low pI forms. This indicates that at least two immunochemically distinct categories of isoenzymes are present in both plasma and intestine. Furthermore, the properties of the differenct CarbE isoenzymes with regard to inhibition by selected organophosphorus compounds were studied in vitro and in vivo. With some exemption the inhibition constants showed small differences between isoenzymes. Subcutaneous and intraperitonal administration of paraoxon and diisopropyl phospho fluoridate (DFP) rapidly inhibited the CarbE activity in guinea pig plasma, much higher doses were necessary to obtain a marked inhibition in lung and liver, and about 25 percent of CarbE activity in lung was resistant to inhibition. Gel filtration of lung homogenate after treatment with organophosphorus compuonds showed that CarbE activity in one of the molecular mass fractions was weakly inhibited. This might be due to different subcellular localization of the isoenzymes and thereby reduced accessibility to some of the lung CarbE isoenzyes. The experiments showed that the efficacy for detoxication is a function of the relative affinities of the organophosphorus compounds for CarbEs and acetyl cholinesterase (AChE). For compounds like paraoxon and DFP, with lower affinities for AChE than for CarbEs, also the lung and liver CarbEs contribute to the detoxication process. The distributions of CarbEs in separated rat liver cells were investigated by polyacrylamide gel electrophoresis (PAGE). All of the liver CarbE isoenzymes could be detected in the parenchymal cells, whereas in both Kupffer cells and endothelial cells only those with pI 6.4/6.2, also termed mono acylglyceral lipase, could be detected.

ETHOLOGY IN SPACE, A UNIQUE OPPORTUNITY FOR BEHAVIOURAL SCIENCE
R. E. Stark and S. R. Heerd, ed. Mar. 1993 99 p
(ESA-STM-246; ISBN-92-9092-208-7; ETN-93-94410) Copyright Avail: CASI HC A05/MF A02

The current status of experiments performed under space flight conditions using animals as subjects is reviewed and summarized. Some potential experimental approaches to study the behavioral responses and acclimatization of animals to the space environment are proposed. Future areas of required behavioral research are presented, and some of the peculiarities associated with the development of a life science experiment and its equipment specifically for behavioral studies in space are shown. The following are also advertized: the availability of the space environment to the European behavioral science community, to encourage behavioral scientists to think in terms of experimentation under microgravity conditions and to stimulate them in generating new ideas and proposals for flight experiments. Relationships for predicting phytoplanktonic absorption at 676 and 436 nm from chlorophyll alpha concentration have been developed for distinct geographic regions defined by latitude. The forms of the predictive equations are controlled by underlying biological mechanisms and lend insight into these mechanisms. Development of these region-specific models allows prediction of phytoplanktonic absorption from more easily measured parameters such as chlorophyll alpha concentration or in situ fluorescence and increases accuracy in modelling optical properties or primary production rate using specific absorption coefficients. Temperate and tropical regions exhibited nearly identical relationships at low chlorophyll so these regions were combined and treated as one. DTIC

MEDICAL EVALUATIONS ON THE KC-135 1991 FLIGHT REPORT SUMMARY
Charles W. Lloyd Aug. 1993 240 p
(NASA-TM-104755; S-692; NAS 1.15:104755) Avail: CASI HC A11/MF A03

The medical investigations completed on the KC-135 during FY 1991 in support of the development of the Health Maintenance Facility and Medical Operations are presented. The experiments consisted of medical and engineering evaluations of medical hardware and procedures and were conducted by medical and engineering personnel. The hardware evaluated included prototypes of a crew medical restraint system and advanced life support pack, a shuttle orbiter medical system, an airway medical accessory kit, a supplementary extended duration orbiter medical kit, and a surgical overhead canopy. The evaluations will be used to design flight hardware and identify hardware-specific training requirements. The following procedures were evaluated: transport of an ill or injured crewmember at man-tended capability, surgical technique in microgravity, transfer of liquids in microgravity, advanced cardiac life support using man-tended capability Health Maintenance Facility hardware, medical transport using a model of the assured crew return vehicle, and evaluation of delivery mechanisms for aerosolized medications in microgravity. The results of these evaluation flights allow for a better understanding of the types of procedures that can be performed in a microgravity environment. Author (revised)

CALCITONIN CONTROL OF CALCIUM METABOLISM DURING WEIGHTLESSNESS Final Report
Karam F. A. Soliman 1993 6 p
(Grant NAG2-411)
(NASA-CR-193622; NAS 1.26:193622) Avail: CASI HC A02/MF A01

The main objective of this proposal is to elucidate calcitonin role in calcium homeostasis during weightlessness. In this investigation our objectives are to study: the effect of weightlessness on thyroid and serum calcitonin, the effect of weightlessness on the circadian variation of calcitonin in serum and the thyroid gland, the role of light as zeitgeber for calcitonin circadian rhythm, the circadian pattern of thyroid sensitivity to release calcitonin in response to calcium load, and the role of serotonin and norepinephrine in the control of calcitonin release. The main objective of this research/proposal is to establish the role of calcitonin in calcium metabolism during weightlessness condition. Understanding the mechanism of these abnormalities will help in developing therapeutic means to counter calcium imbalance in spaceflights. Derived from text

GENDER DIFFERENCES IN ENDOCRINE RESPONSES TO POSTURE AND 7 DAYS OF 6 DEG HEAD DOWN BED REST

J. Vernikos, M. F. Dallman (California Univ., San Francisco.), L. C. Keil, D. OHara, and V. A. Convertino (National Aeronautics and Space Administration. John F. Kennedy Space Center, Cocoa Beach, FL.) Feb. 1993 20 p
(RTOP 199-18-12-09)
(NASA-TM-103991; A-93016; NAS 1.15:103991) Avail: CASI HC A03/MF A01

Endocrine regulation of fluids and electrolytes during seven days of 6 deg head down bed rest (HDBR) was compared in male (n = 8) and, for the first time, female (n = 8) volunteers. The subjects' responses to quiet standing for 2 hr before and after HDBR were also tested. In both sexes, diuresis and natriuresis were evident during the first 2-3 days of HDBR, resulting in a marked increase in the urinary Na/K ratio and significant Na retention on reambulation. After the first day of HDBR, plasma renin activity (PRA) was increased relative to aldosterone, plasma volume was decreased, and the renal response to aldosterone appeared to be appropriate. Circulating levels of arginine vasopressin (AVP), cortisol, and ACTH were unchanged during HDBR. Plasma testosterone decreased slightly on day 2 of HDBR in males. The ratio of AM ACTH to cortisol was lower in females than in males because ACTH was lower in females. Urinary cortisol increased and remained elevated throughout the HDBR in males only. There were no gender differences in the responses to 7 day HDBR, except those in the pituitary-adrenal system; those differences appeared unrelated to the postural change. The provocative cardiovascular test of quiet standing before and after bed rest revealed both sex differences and effects of HDBR. There were significant sex differences in cardiovascular responses to standing, before and after HDBR. Females had greater PRA and aldosterone responses to standing before bedrest and larger aldosterone responses to standing after HDBR than males. Cardiovascular responses to standing before and after bedrest differed markedly: arterial pressure and heart rates increased with standing before HDBR, by contrast, arterial pressure decreased, with greater increases in heart rates after HDBR. In both sexes, all hormonal responses to standing were greater after HDBR. The results show clearly that similar responses to standing as well as to HDBR occur in both sexes, but that females exhibit greater PRA and aldosterone responses than males. Author (revised)

PHASE-SHIFTING EFFECT OF LIGHT AND EXERCISE ON THE HUMAN CIRCADIAN CLOCK Annual Report, 1 Mar. 1991 - 28 Feb. 1993
Eve V. Cauter 18 May 1993 19 p
(Grant AF-AFOSR-0222-90)
(AD-A265732; AFOSR-93-0378TR) Avail: CASI HC A03/MF A01

The aim of the present study was to determine the magnitude and direction of immediate phaseshifts of human rhythms following a single exposure to a 3-hour pulse of bright light or physical activity. The pulse of light or activity was presented under constant routine conditions and measurement of the resultant phase-shifts were performed under the same constant routine conditions on the first day following pulse presentation. Four overt rhythms that are strongly dependent on circadian timing, i.e., the rhythms of plasma cortisol, plasma TSH, plasma melatonin, and body temperature, were monitored. Based on the analysis of the TSH profiles, our findings indicate that exposure to light around the time of the minimum of body temperature results in phase-advances averaging less than one hour in magnitude. Exposure to light approximately 3 hours before the time of the minimum of body temperature results in 1-2 hour phase delays. Preliminary analyses of the melatonin profiles confirm these observations. Our findings regarding the effects of exercise are still inconclusive. DTIC

CELLULAR MECHANISM OF TURNOVER OF THE STRESS INDUCED PROTEIN HSP 70 Annual Report, 15 Apr. 1992 - 14 Apr. 1993
Nancy Petersen 17 May 1993 8 p
(Contract F49620-92-J-0234)
(AD-A265723; AFOSR-93-0383TR) Avail: CASI HC A02/MF A01

Synthesis of the heat shock protein, hsp7O, appears to be essential for recovery from heat and chemical stress. Both because of the role of this protein in cellular recovery from stress and because of the possibility of using levels of hsp7O synthesis or accumulation as a measurement of cellular response in stress, it is important to study the stability of hsp7O. We have shown that Drosophila hsp7O decays in vitro by an autoproteolytic mechanism. Autoproteolytic decay could be part of the feedback mechanism regulating the levels of hsp7O accumulation if it occurs in vivo. To determine whether autoproteolytic decay is occurring in vivo, we propose to identify the in vivo breakdown products of hsp7O and to compare their N-terminal sequences to those of the in vitro breakdown products. Precisely the same cutting site would indicate that the same protease may be responsible for the decay in both cases. We will also determine the site of the protease activity in hsp7O for the in vitro decay. DTIC

READINESS TO PERFORM TESTING: A CRITICAL ANALYSIS OF THE CONCEPT AND CURRENT PRACTICES Final Report
Kirby Gilliland and Robert E. Schlegel Aug. 1993 77 p
(Contract DTFA02-92-P-23499)
(DOT/FAA/AM-93/13) Avail: CASI HC A05/MF A01

Readiness to Perform (RTP) testing has become an increasingly popular alternative to biochemical screening as a method for assessing risk factors (i.e., drug, alcohol, fatigue, etc.) in the workplace. The focus of RTP testing is on the assessment of worker performance capability prior to job engagement. Thus, RTP testing is a method of assessing the state of preparedness of workers for performing their jobs. Unfortunately, RTP testing is being distributed and applied in the workplace despite a lack of knowledge regarding its conceptual basis and use. A project that investigated the conceptual and methodological foundations of RTP testing is summarized. Based on their expertise and background in task battery research, development, and validation, the authors explored the principles and empirical research on which the concept and methods of RTP testing appear to be based. This evaluation included literature reviews, methodological assessments, and an analysis of popular RTP measures. First, a brief review of some of the background for RTP testing is provided and the difficult task of defining RTP is attempted. Specific issues and problems in conceptualizing and implementing RTP testing are addressed. Among the numerous issues addressed are the more important comprehensive factors of determining the appropriate criteria for RTP prediction and establishing the validity of RTP through various forms of empirical research. In addition, a number of the problems associated with implementing RTP testing are presented. Some examples of these problems are: testing methodology, comparative standards, time limits in testing, general versus restricted populations, and the hidden costs of RTP testing. Finally, two supporting literature reviews of areas that form the rational foundation for RTP testing are included. One review provides a summary of some of the major computerized performance assessment batteries from which many of the current RTP measures were derived. The other review surveys research literature on the influence of selected risk factors on human performance. Author (revised)

CELLULAR TRACK MODEL FOR STUDY OF HEAVY ION BEAMS
Judy L. Shinn, Robert Katz (Nebraska Univ., Lincoln.), Francis A. Cucinotta, John W. Wilson, and Duc M. Ngo (Old Dominion Univ., Norfolk, VA.) Washington Aug. 1993 15 p
(RTOP 199-45-16-11)
(NASA-TP-3351; L-17231; NAS 1.60:3351) Avail: CASI HC A03/MF A01

Track theory is combined with a realistic model of a heavy ion beam to study the effects of nuclear fragmentation on cell survival and biological effectiveness. The effects of secondary reaction products are studied as a function of depth in a water column. Good agreement is found with experimental results for the survival of human T-I cells exposed to monoenergetic carbon, neon, and argon beams under aerobic and hypoxia conditions. The present calculation, which includes the effect of target fragmentation, is a significant improvement over an earlier calculation because of the use of a vastly improved beam model with no change in the track theory or cellular response parameters. PSYCHOPHYSIOLOGICAL INVESTIGATIONS OF THE BIOMEDICAL PROBLEMS OF MANNED SPACEFLIGHT Final Technical Report, 1 Jan. 1990 - 28 Feb. 1993
15 May 1993 4 p
(Contract NCC2-115; RTOP 199-70-12-14)
(NASA-CR-194107; NAS 1.26:194107) Avail: CASI HC A01/MF A01

The Final Report on psychophysiological investigations of the biomedical

problems of manned spaceflight is presented. In the first project, statistical analyses of human autonomic data were performed. The objectives were the following: to establish a relational data base containing human psychophysiological data obtained from Shuttle flight experiments and ground-based research over a 20 year period; to enable multi-user access and retrieval of these data for subsequent analyses and for possible inclusion in the proposed Life Sciences Data Archive; and to enable/conduct statistical analyses across several experiments on large subject populations which can thereby provide definitive answers to questions on human autonomic and behavioral responses and adaptation to environmental stressors on Earth and in space. The second project studied motion sickness. The objectives were: to test/develop hardware and procedures to be incorporated into preflight training of crewmembers of Spacelab-J; and to examine spin-off applications of AFT. The third project studied orthostatic intolerance. The objective was to test the feasibility of applying autogenic-feedback training as a potential treatment for postflight orthostatic intolerance.

RENAL FUNCTION ALTERATIONS DURING SKELETAL MUSCLE DISUSE IN SIMULATED MICROGRAVITY Final Technical Report, 1 Jan. - 31 Oct. 1992
Bryan J. Tucker 31 Oct. 1992 5 p
(Contract NCC2-556)
(NASA-CR-194258; NAS 1.26:194258) Avail: CASI HC A01/MF A01

This project was to examine the alterations in renal functions during skeletal muscle disuse in simulated microgravity. Although this area could cover a wide range of investigative efforts, the limited funding resulted in the selection of two projects. These projects would result in data contributing to an area of research deemed high priority by NASA and would address issues of the alterations in renal response to vasoactive stimuli during conditions of skeletal muscle disuse as well as investigate the contribution of skeletal muscle disuse, conditions normally found in long term human exposure to microgravity, to the balance of fluid and macromolecules within the vasculature versus the interstitium. These two projects selected are as follows: investigate the role of angiotensin 2 on renal function during periods of simulated microgravity and skeletal muscle disuse to determine if the renal response is altered to changes in circulating concentrations of angiotensin 2 compared to appropriate controls; and determine if the shift of fluid balance from vasculature to the interstitium, the two components of extracelilular fluid volume, that occur during prolonged exposure to microgravity and skeletal muscle disuse is a result, in part, to alterations in the fluid and macromolecular balance in the peripheral capillary beds, of which the skeletal muscle contains the majority of recruitment capillaries. A recruitment capillary bed would be most sensitive to alterations in Starling forces and fluid and macromolecular permeability. Author (revised)

TRANSCRIPT OF WORKSHOP ON MACHINERY HEALTH MONITORING
A. Craggs, ed., R. J. Rogers, ed. (New Brunswick Univ., Fredericton.), and T. N. Moore, ed. (Queens Univ., Kingston, Ontario.) Mar. 1992 75 p
Workshop held in Calgary, Alberta, 27 Sep. 1988 Sponsored by National Research Council of Canada, Ottawa, Ontario
(IME-MET-TR-005; NRC-33557; CTN-93-60783) Avail: CASI HC A04/MF A01

At a workshop on machinery health monitoring, 15 speakers presented short, prepared talks on topics including vibration monitoring, plant machinery diagnostics, use of test equipment and interpretation of results, economic benefits of monitoring, expert systems, bearings, research programs, sensors, vibration frequency spectral analysis, vibration reduction, liner cavitation damage in engines, predictive and preventive maintenance, standards, and training. After the prepared talks, a free-ranging discussion explored the points introduced in the formal presentations and also addressed additional areas of concern. A transcript of the prepared talks and discussion session is presented. CISTI

CIRCADIAN RHYTHMS DURING SIMULATION OF THE D2-SPACEFLIGHT Ph.D. Thesis - Tech. Hochschule Aachen [ZIRKADIANE RHYTHMIK BEI DER SIMULATION DES D-2-WELTRAUMFLUGES]
Henning Allmers Sep. 1992 148 p In GERMAN
(DLR-FB-92-27; ETN-93-93958) Avail: CASI HC A07/MF A02

Eight subjects were isolated from the outside world for 26 days, during which two time zone shifts were performed and seven days of six degree down tilt were achieved simulating weightlessness. The results show that the method to achieve time zone change by gradually shortening the day for one hour over a period of seven days is a valid procedure to accomplish a seven hour time zone shift in a easterly direction for some body functions such as heat rate and sodium excretion. Other parameters such as temperature and hydroxylmelatoninsulfate excretion only adapted during weightlessness simulation. The results show that the method did not achieve ideal adaptation of all circadian rhythms in the evaluated parameters at the simulated spaceflight launch date. ESA

Canada's Department of National Defence established the Associate Committee on Aviation Medical Research in 1939 and laboratory studies in pressure physiology began in Toronto. In 1940, research efforts were expanded with the formation of the No. 1 Clinical Investigation Unit, where a low-temperature low-pressure chamber was constructed to support research on human capabilities under cold and high-altitude conditions. The Unit was also the site of the first human centrifuge in the allied countries, which was used to develop the world's first anti-G flying suit to go into service. After the war, research in aviation medicine continued at the universities and at the Unit, now renamed the Royal Canadian Air Force Institute of Aviation Medicine. In 1968, this institute was again renamed to become the Canadian Forces Institute of Environmental Medicine (CFIEM). In 1971, CFIEM was merged with Defense Research Establishment Toronto to form the Defense and Civil Institute of Environmental Medicine (DCIEM). The history of DCIEM and its forerunners is presented in pictorial form, showing highlights of research activities and research facilities.

PHYSICAL COUNTERMEASURES FOR LONG-TERM MANNED SPACE FLIGHTS
A. Gueell, G. Tallarida, H. Wegmann, and C. Barron, ed. Feb. 1993 93 p
(ESA-SP-1160; ISBN-92-9092-077-7; ETN-93-94409) Copyright Avail: CASI HC A05/MF A01

The physiological data that provide the most accurate description of the medical problems encountered during long term space flight, and data indicating a need for countermeasures to ameliorate the safety of astronauts, are ascertained. Ground studies that will best serve as a basis for future flight protocols are discussed. Physical countermeasures used during past safe flights are listed and new approaches are proposed. The need for long term bed rest studies necessary to gain more fundamental knowledge about the adaptive processes that occur during weightlessness, and to validate the ability of various proposed countermeasures to counteract these mechanisms is indicated. THYROID ALTERATIONS IN PORCINE AFTER PROLONGED EXPOSURE TO COLD OR HEAT

Bruce A. Young, Sarah J. Cosgrove, and Robert J. Christopherson 1992 28 p
(DA Proj. MM3-3-C-30)
(AD-A266840; NMRI-92-130) Avail: CASI HC A03/MF A01

Studies by the Naval Medical Research Institute on humans after prolonged Antarctic residence have shown possible intracellular thyroid hormone alternations. These studies demonstrated a rise in serum clearance of orally administered triiodothyronine (T3), T3 production, and T3 total volume distribution in naval personnel after a 42 week residence in Antarctica compared to a control period in California. The increased serum clearance and total pool of T3 indicated a possible intracellular response which could not be further investigated using human subjects. An animal model permitted prolonged confinement of subjects in temperature controlled chambers and the use of radioisotopes to label T3. DTIC

THE EFFECTS OF EVALUATION AND PRODUCTION BLOCKING ON THE PERFORMANCE OF BRAINSTORMING GROUPS M.S. Thesis
Kevin D. Osten Aug. 1992 72 p Limited Reproducibility: Document partially illegible
(AD-A265495; AFIT/CI/CIA-92-134) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Evaluation apprehension and production blocking have been identified as possible factors leading to the reduced performance of brainstorming groups. In some experiments, high evaluation led to reduced group performance, while in other experiments performance was unaffected. The present experiment examined the effects of outside evaluation and production blocking of group performance. The resulting 2 x 2 design used responses from 171 introductory psychology students, run in same-gender groups of three. Contrary to the evaluation apprehension hypothesis, evaluation level had no significant adverse effect on group performance. In support of the production blocking hypothesis, low production blocking groups generated significantly more ideas than high production blocking groups. Satisfaction with the group experience and satisfaction with individuals and group performance were also examined. Explanations for the results are discussed as well as limitations and suggestions for future research. DTIC

WORK/REST SCHEDULES AND PERFORMANCE OF S-3 AVIATORS DURING FLEET EXERCISE
David F. Neri and Scott A. Shappell Mar. 1993 18 p
(AD-A265807; NAMRL-1382) Avail: CASI HC A03/MF A01

We examined the effect that a fleet exercise has on the work/rest patterns, fatigue, and cognitive performance of S-3 aviators. For 10 days during Fleet Exercise 1992, twenty-one S-3 aviators from Carrier Air Wing Seventeen (CVW-17) aboard USS Saratoga (CV-60) completed detailed daily-activity logs while performing their usual tasks. Subjective measures of fatigue, quality of rest, and sleep need were also collected. A subset of eight aviators completed a brief battery of computer tasks as soon before flying as possible and again after flight debrief. Results indicated that,

although the fleet exercise appeared to be below average in difficulty, there were statistically significant performance changes from pre- to postflight on a fatigue-sensitive reaction time task. Average sleep onset was delayed over the course of the fleet exercise, peaking at past 0300 by day 8. A continuation of this pattern could lead to circadian desynchrony and serious sleep problems. Responses to questions on fatigue, sleep need, and readiness to fly a strike mission were consistent with circadian factors. Further research in this area is needed to determine the magnitude and extent of this problem. We recommend that additional data be collected on a variety of fleet exercises with particular effort made to include S-3 squadrons affected by the reductions in manning and increased tasking. The additional data will provide an objective means of fully evaluating the impact of these operational changes on the S-3 community. DTIC
